Resumen

En el presente estudio se realizó una revisión taxonómica del género *Hypseocharis* en Bolivia y Perú. Se analizó la diversidad morfológica abarcando toda la distribución geográfica del género *Hypseocharis* utilizando 105 especímenes de herbario. Un análisis multivariado morfométrico fue aplicado a 24 individuos completos para evaluar los caracteres históricos utilizados para diferenciar las especies dentro del género. La revisión del material de herbario mostró una distinción de la especie *H. tridentata*, pero no se confirmó una clara separación entre las "especies" *H. bilobata*, *H. malpasensis*, *H. pedicularifolia* y *H. pimpinellifolia*. Todas ocupan el mismo morfo espacio con similares caracteres morfológicos, apoyando previos estudios en Argentina, donde solamente se describieron dos especies: *H. pimpinellifolia* y *H. tridentata*, esta última proveniente de Argentina y con solo un espécimen de Bolivia. Nuestros resultados también mostraron que *H. pilgeri*, originalmente descrita en Perú, tampoco se diferencia de *H. pimpinellifolia*. Por lo tanto, proponemos la distinción de solamente dos especies en el género: *H. pimpinellifolia* con hojas variables pinnadas o bipinnadas, con foliolos terminales un poco más grandes que los foliolos laterales; flores con 15 anteras y tipo de fruto capsular. Mientras que *H. tridentata* posee hojas pinnadas con foliolos terminales mucho más grandes que los laterales; flores con 5 anteras y tipo de fruto esquizocarpo. *Hypseocharis pimpinellifolia* es una especie ampliamente distribuida desde Ancash (Perú) hasta La Rioja (Argentina) morfológicamente variable incluyendo varios tipos de hojas, desde simples pinnadas hasta bipinnadas y flores blancas, amarillas, naranjas o rojas.

Abstract

In the present study we revised the genus *Hypseocharis* in Bolivia and Peru. A total number of 105 herbarium specimens were revised to evaluate the morphological diversity across the range of the genus. In a subset of 24 complete individuals a multivariate morphometric analysis was performed to evaluate the morphological characters historically used to differentiate the "species" of the genus *Hypseocharis*. A revision of the herbarium material indicated that there are no sharp lines dividing the different "species" with the only exception of *H. tridentata*. The multivariate analysis indicated that *H. bilobata*, *H. malpasensis* and *H. pedicularifolia* all occupy the same morphospace as *H. pimpinellifolia* and there are no individual morphological characters or suites of characters permitting the differentiation of distinct taxa. This confirms earlier findings from Argentina: There are only two species in the genus, widespread *Hypseocharis pimpinellifolia* and *H. tridentata*. *Hypseocharis pilgeri*, originally described from Peru, can also not be differentiated from *H. pimpinellifolia*. We propose the recognition of only two species: *H. pimpinellifolia* with variously pinnate to bipinnate leaves with a terminal leaflet at most marginally larger than the lateral ones, flowers with 15 anthers and capsular fruits as differing from *H. tridentata* with pinnate leaves with the terminal leaflet much larger than the lateral ones, flowers with 5 anthers and schizocarpic fruits. *Hypseocharis pimpinellifolia* is a widespread and polymorphic species, ranging from Ancash (Peru) to La Rioja (Argentina) and comprises forms with white, yellow, orange, and red corollas and with simply pinnate to very finely bipinnate leaves.

Introduction

Hypseocharis J. Rémy is a genus endemic to middle to high elevations of the Andes (ca. 2000–4200 m) ranging from Peru to Argentina (Figure 1). In Bolivia it occurs along the eastern Cordillera of the Andes in the Puna, and Pre-puna regions, and in dry valleys between 2500 and 3800 m. It is usually found in open habitats, often on shallow soils in Andean grasslands and between rocks.

The genus was first described by Rémy (1847) and placed in the family Geraniaceae. Knuth (1930) recognized three genera within Oxalidaceae R. Br: *Oxalis* L., *Biophytum* DC and *Hypseocharis*, and he differentiated them based on habit, leaf morphology, the number of stamens and style morphology. Systematics of *Hypseocharis* have been controversial. Cronquist (1981) considered the genus as a link between the Oxalidaceae and Geraniaceae, while Boesewinkel (1988) analyzed the seed structure and affirmed that the genus is closer related to Geraniaceae than to Oxalidaceae. Subsequent studies on floral anatomy demonstrated that *Hypseocharis* should be placed in Geraniaceae (Devi, 1991). Price and Palmer (1993) confirmed that placement with molecular data (*rbcL*-phylogeny) and Palazzi et al. (2012) retrieved *Hypseocharis* as sister to core-Geraniaceae and suggested resurrecting the family Hypseocharitaceae Wedd. (Weddell in 1857), based on both the phylogenetic position and the aberrant morphology (especially the capsular fruit).

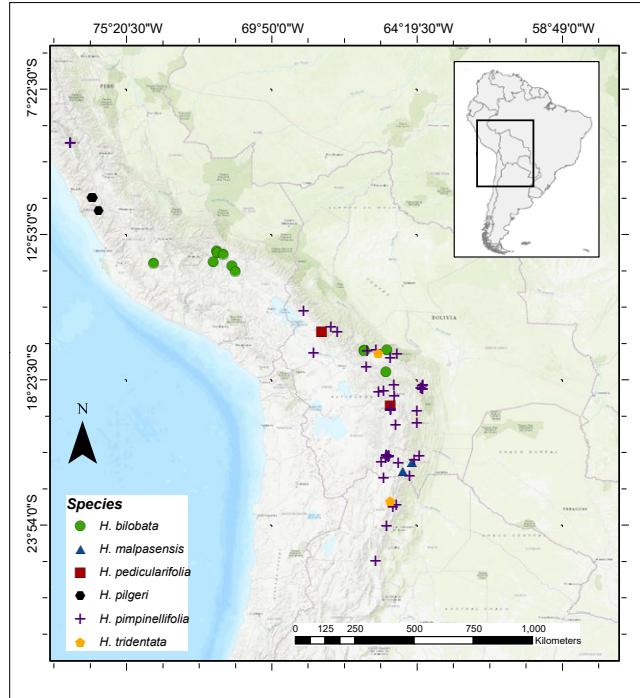

Figure 1. Distribution of the genus *Hypseocharis* in South America

Currently, six species are recognized in the genus according to the Tropicos website (Missouri Botanical Gardens): *Hypseocharis bilobata* Killip, *H. malpasensis* R. Knuth, *H. pedicularifolia* R. Knuth, *H. pimpinellifolia* J. Rémy, *H. pilgeri* R. Knuth, and *H. tridentata* Griseb. while

H. corydalifolia, R. Knuth, *H. fiebrigii* R. Knuth, *H. moschata* R. Knuth and *H. pimpinellifolia* var. *punicea* Kuntze are considered as synonyms (<http://www.tropicos.org>, accessed 01.08. 2019). All six accepted species, apart from *H. pilgeri*, are reported in the Checklist of the Flora of Bolivia (Jørgensen et al. 2014). Macbride (1949) reported four species from Peru: *H. bilobata*, *H. pedicularifolia*, *H. pilgeri* and *H. tridentata* mainly based on leaflets morphology and number of flowers per peduncle. These authors did not consider the number of stamens, flower color or type of fruit to distinguish the four species.

Slanis and Grau (2001) provided the only recent, critical revision of the genus, focusing on material from Argentina. They proposed the recognition of only two species, namely *H. pimpinellifolia* and *H. tridentata* not only considering leaf morphology, but also including number of stamens and type of fruit. Slanis and Grau (2001) also emphasized that the taxonomy of the species in Bolivia and Peru requires critical work and voiced their suspicion that species limits as currently accepted are incorrect. The aim of the present study is to critically revise the genus for the area not covered by Slanis and Grau (2001), i.e., Bolivia and Peru.

Material and methods

A total of 105 specimens mainly from the Herbario Nacional de Bolivia (La Paz, LPB), the Herbario de la Universidad Nacional Mayor de San Marcos (Lima, USM), Field Museum of Natural History (Chicago, F) and Muséum National d'Histoire Naturelle (France, P) were critically revised. Additional material was seen in BOLV, HUT, MO, P, US, BONN, F, B, K, GH, NHA, CORD, SI, LIL (herbarium acronyms follow Thiers 2019). Seeds collected in Bolivia (Ortuño 1361) were germinated in Bonn University Botanic Gardens and taken into cultivation and a population of the putative Peruvian endemic "*H. pilgeri*" (Peru, Department Lima) was studied in the field.

Vegetative and reproductive morphological characters were qualified and quantified from a subset of specimens from Bolivia representing all character combination used to delimit putative species based on key from Flora of Peru (Macbride, 1949) and classification key of *Hypseocharis* in Argentina (Slanis & Grau, 2001). Specimens were assigned to taxa based on the technical characters used in the literature and based on a comparison to type specimens, where available. *Hypseocharis* is generally poorly represented in herbaria, probably due to its very short flowering time, high elevation habitat and the technical problems of preparing good specimens due to the rosulate habit and very deep-seated roots. Only specimens showing all relevant characters were included in the analysis.

Qualitative characters were described according to The Cambridge Illustrated Glossary of Botanical Terms (Hickey, King, & King, 2000). Three leaves per specimen were selected according to size (big, medium and small) and one of them (generally the largest one) was used to characterize the leaflets (width and length measurements). From flowers, petal diameter, number of flowers

per peduncle, number and length of stamens were measured, and we included types of trichomes present in the ovary as well. Finally, type of fruit was characterized according to Slanis and Grau (2001) into capsule or schizocarp (Supp. Table A1). The morphological data matrix was analyzed with Principal Component Analysis (PCA) in 24 individuals in total, using the open source software R (R Core Team, 2019) with a previous logarithm transformation to account for differences in unit measurements. Taxonomic descriptions were complemented by the inclusion of specimens from Peru, Bolivia and Argentina.

Results and discussion

A total of 24 Bolivian specimens were quantitatively analyzed corresponding to 5 “species” as described by Knuth (1908): *Hypseocharis pimpinellifolia* (n=13), *H. bilobata* (n=2), *H. malpasensis* (n=2), *H. pedicularifolia*

(n=2) and *H. tridentata* (n=5) (Supp. Table A1).

Three types of leaves: pinnate, bipinnate and bipinnate with ternate leaflets (Supp. Figure A1) and two types of trichomes located on the ovary were identified: simple and glandular ones (Figure 6G). A summary of the main reproductive and vegetative characters is presented in Table 1. *Hypseocharis pimpinellifolia* presented a high variability in leaf type and flower color; while *H. tridentata* differed from the remaining specimens in the number of stamens and type of fruit (Table 1). Principal Component Analysis showed similar results based on a combination of quantitative vegetative and reproductive characters, depicting a clear separation of *H. tridentata* (Figure 2). The first five components accounted for 90% of the total variation. The first component was mainly explained by peduncle length; while the second component was mainly explained by leaf length and number of leaflets (Table 2, Figure 2).

Table 1. Summary of reproductive and vegetative variables measured in *Hypseocharis* specimens from Bolivia. Hyphenated species names assigned to technical characters used in the literature (Sch: Schizocarp, VC: Ventricidal Capsule; P: Pinnate, BP: Bipinnate, BPTl: Bipinnate with ternate leaflets; W: White, Y: Yellow, O: Orange, R: Red; G: Glandular, S: Simple).

Species	n	Stamens number		Fruit type		Leaf type			Flower color				Trichomes on ovary	
		5	15	Sch	VC	P	BP	BPTl	W	Y	O	R	G	S
<i>H. tridentata</i>	5	X			X	X			X				X ^a	
<i>H. pimpinellifolia</i>	15		X		X	X	X	X	X	X	X	X	X	X
“ <i>H. bilobata</i> ”	3	X		X	X	X		X	X				X	X
“ <i>H. malpasensis</i> ”	2		X		X ^b	X		X		X	X			X
“ <i>H. pedicularifolia</i> ”	2	X			X		X	X			X	X	X	
“ <i>H. pilgerii</i> b”	4		X		X		X		X				X	X

^aData taken from Slanis and Grau 2001

^bWeigend (pers. obs.)

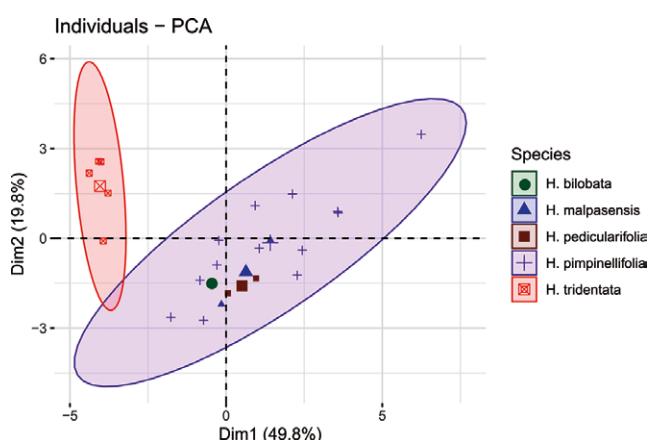

Figure 2. Principal Component Analysis (PCA) based on vegetative and reproductive traits from the five “species” of *Hypseocharis* in Bolivia. Species names assigned based on technical characters as used in the literature. There is no clear separation of any of the species apart from *H. tridentata*. First component explain 49.8% of the total variation and separate individuals mainly based on peduncle length while second component explains 19.8% and is based on vegetative characters of leaf length and number of leaflets. See details in Table 2.

Table 2. Proportional contribution of variables for the first five PCA components. Vegetative characters mainly explain by the second and fifth components, while reproductive ones are explained by components one, three and four. Numbers in bold show the highest contribution to the correspondent component.

	PCA 1	PCA 2	PCA 3	PCA 4	PCA 5

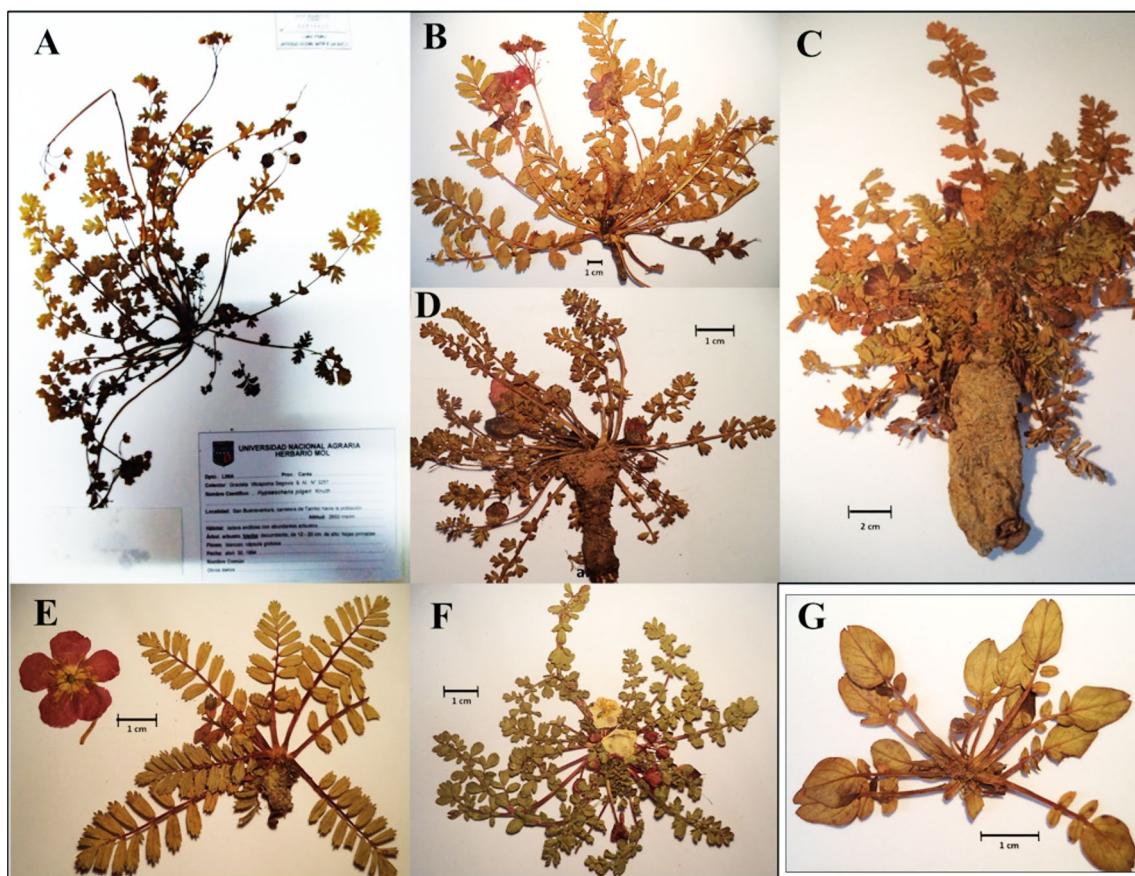

Figure 5. Proposed division of species of the genus *Hypseocharis* (species names assigned based on technical characters as used in the literature). **A-F** *Hypseocharis pimpinellifolia*. Synonyms of *H. pimpinellifolia*: *H. pilgeri* (**A**), *H. pedicularifolia* (**D**), *H. malpasensis* (**E**), *H. bilobata* (**F**). **G** *H. tridentata*. **A:** *H. "pilgeri"* (Graciela Vilcapoma Segovia & al. 3257, USM); **B:** *H. pimpinellifolia* (Caro-Rojas 1564, LPB); **C:** *H. pimpinellifolia* (Evert Thomas ET131, LPB); **D:** *H. "pedicularifolia"* (R. Ehrich 63, LPB); **E:** *H. "malpasensis"* (Beck St. G. 26091, LPB); **F:** *H. "bilobata"* (Beck St. G. 16849, LPB); **G:** *H. tridentata* (R. Baar 256, LPB). Photos M. Weigend, USM (A), S. Lozada-Gobilard, LPB (B-G).

Hypseocharis tridentata is not as common and widespread as *H. pimpinellifolia* (Figure 1), but it is morphologically highly differentiated with terminal leaflets distinctively larger than the lateral ones, with a tridentate apex or emarginate with a medial mucro or tooth (Figure 4, Figure 5, Figure 6; Macbride 1949; Slanis & Grau 2001). *Hypseocharis tridentata* also differs in both flower and fruit morphology (Table 1): It differs from *H. pimpinellifolia* by 5 stamens per flower (versus 15) and a schizocarpic fruit with five dehiscent mericarps and 1- few seeds per locule versus a ventricidal capsule (Slanis & Grau 2001, Figure 3). The only specimen of *H. tridentata* present in the LPB Herbarium plus four specimens from BOLV Herbarium corresponded to the published descriptions of the fruit (Figure 4).

Additionally, a comparison of cultivated material of "*H. pimpinellifolia*" from La Paz (Ortuño 1361) with an observation of living plants of "*H. pilgeri*" at Canta (Dept. Lima, Weigend & Peña Ramos 9715) showed no differences whatsoever in leaf dissection, flower morphology or indument (Figure 6C-E). A comparison of additional material from Lima clearly confirmed that *H.*

pilgeri cannot be differentiated from *H. pimpinellifolia* (Figure 5A-F).

Conclusion

Overall, we confirm and expand the observations by Slanis and Grau (2001) from Argentina: *H. pimpinellifolia* is a highly variable species with regards to details of leaf dissection and flower colour, but the recognition of additional taxa is not warranted. All specimens seen from Argentina to northern Peru belong to a morphological continuum and are best recognized as belonging to a single species. Bolivian *H. malpasensis*, *H. pedicularifolia*, and *H. bilobata* and Peruvian *H. pilgerii* are therefore synonymized with *H. pimpinellifolia*. *Hypseocharis pimpinellifolia* and *H. tridentata* are recognized as the only two species in the genus. There are some differences in leaf dissection and flower color, which – at face value – might warrant the recognition of intraspecific entities. However, there is no clear geographical pattern in the distribution of different “morphs” and the differentiating characters do not appear to be at all combined in any meaningful way, as the statistical analysis shows.

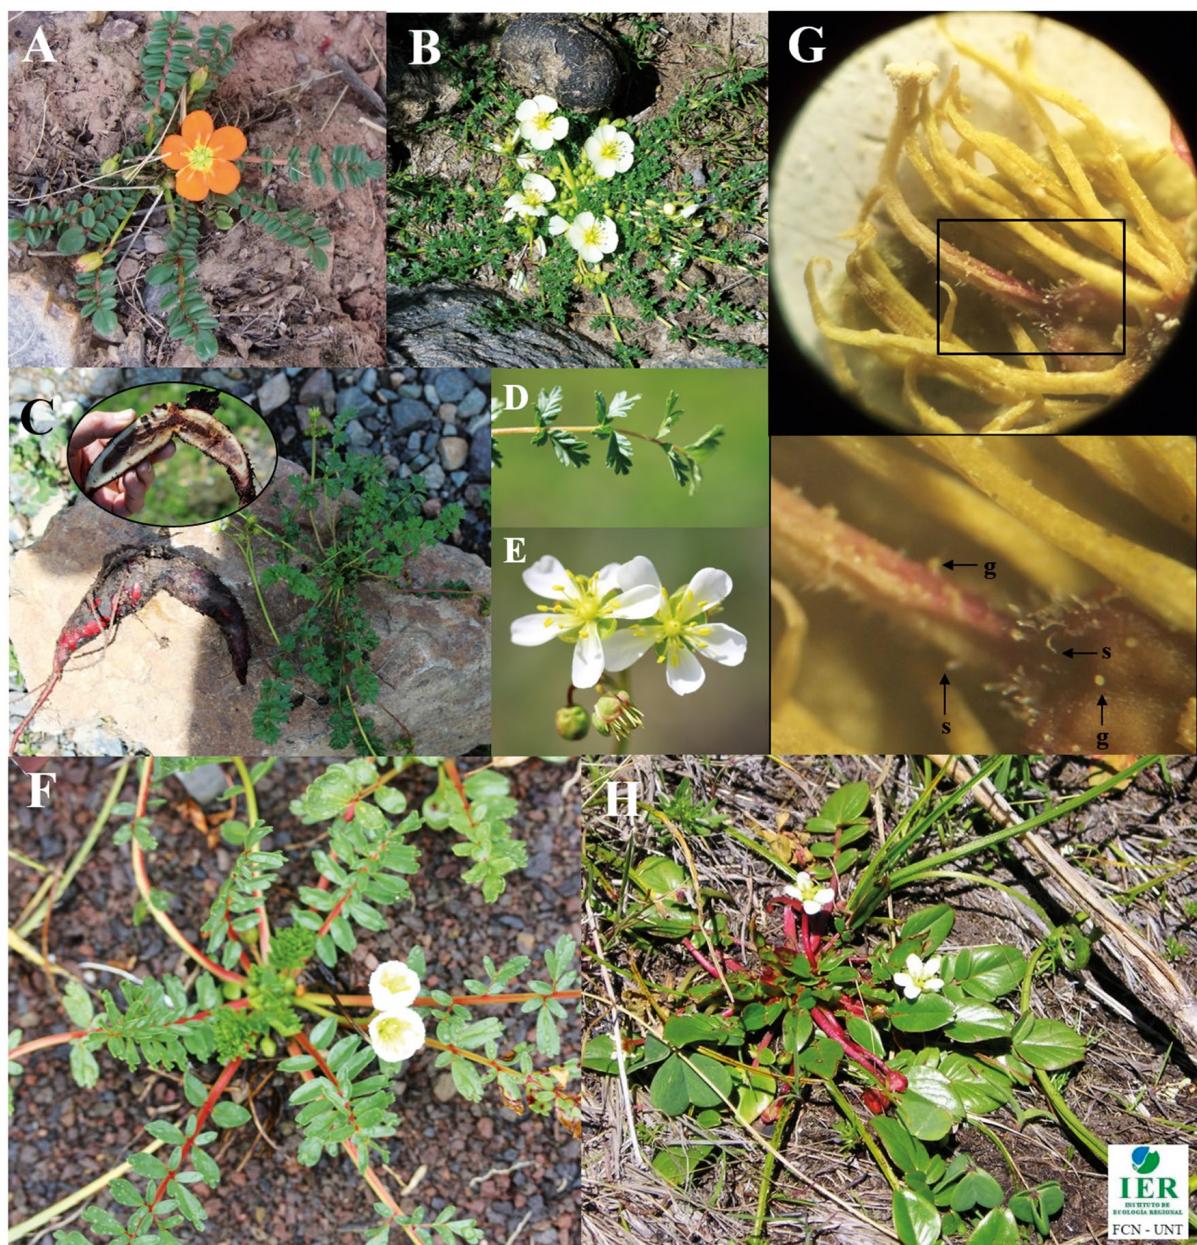

Figure 6. Comparison of the proposed species of the genus *Hypseocharis* based on vegetative and reproductive traits. **A-G** *Hypseocharis pimpinellifolia*. Synonyms of *H. pimpinellifolia*: *H. pilgeri* (**C-E**), *H. bilobata* (**F**). **H** *Hypseocharis tridentata*. *H. pimpinellifolia* presents a high diversity, leaves can be pinnate (**A**), bipinnate (**B**, **D**) or bipinnate with ternate leaflets (**F**) (See Supplementary Figure A1 for detailed drawings). Flowers possess 15 stamens with separate (**E**) or close petals (**A**, **B**, **F**), orange (**A**) or white (**B**, **E**, **F**), but also can be yellow or red. Ovary possess simple (*s*), glandular (*g*) or both types of trichomes (**G**). On the other hand, leaves of *Hypseocharis tridentata* are pinnate with the terminal leaflet distinguished larger than the rest and flowers are white with 5 stamens only (**G**). Photos: Teresa Ortuño (**A**), Alfredo Grau (**B**) M. Weigend (**C-F**), S. Lozada-Gobilard (**G**). Used with permission from AA. M. Anton and F. O. Zuloaga (directors), Flora Argentina. 28th November 2019 <http://www.floraargentina.edu.ar> (**H**).

Key to the species of *Hypseocharis*

Leaves pinnate, up to 2 cm long, terminal leaflet much larger than lateral leaflet; flowers with 5 stamens, petals white; fruit a schizocarp with five 1-seeded mericarps
H. tridentata

Leaves pinnate, bipinnate or bipinnate with ternate leaflets, (1-)5—13 cm long, terminal leaflet marginally larger than lateral leaflets; flowers with (12-)15 stamens, petals white, yellow, orange or red; fruit a ventricidal capsule
H. pimpinellifolia

Formal taxonomy

Hypseocharis pimpinellifolia J. Rémy -- Ann. Sci. Nat., Bot. sér. 3, 8: 239. 1847 [Oct 1847].

Type:-- BOLIVIA, Santa Cruz, Prov. Valle Grande, in dry grassland of the high Andes by the Río Grande, not far from Puccara, at 3000 m, D'Orbigny 1137 (P00835307!).

= *Hypseocharis bilobata* Killip -- J. Wash. Acad. Sci. 16: 570. 1926. Holotype:-- PERU, Cuzco, 3000–3600 m, F. L. Herrera s.n. (US00101084!).

= *Hypseocharis corydalifolia* R. Knuth -- Bot. Jahrb. Syst. 41(3): 173. 1908. Holotype:-- ARGENTINA, Prov. Catamarca, near Capillitas, anno 1878, Schickendantz 306 (B†; isotype: CORD00002963!).

= *Hypseocharis fiebrigii* R. Knuth -- Bot. Jahrb. Syst. 41(3): 173. 1908. Holotype:-- BOLIVIA, Cuesta Vieja, at 3100 m, Fiebrig 3296 (B†).

= *Hypseocharis malpasensis* R. Knuth -- Repert. spec. nov. Regni Veg. 29: 219. 1931. Lectotype (here designated):-- BOLIVIA, Chuquisaca, Prov. Zudañes Cuesta de Malpaso, Cordillera de Sombrero, 3100 m, anno 1927, C. Troll 797 (B 10 0002189!), isotypes: 2 specimens; holotype: M 0172361!.

= *Hypseocharis moschata* R. Knuth -- Meded. Rijks-Herb. 27: 67. 1915. Type:-- BOLIVIA, on short-grassed alpine meadows of the Sunchalkammes, ca. 2900 m, 04.1911, T. Herzog 2013 (Z-000017708!; L.2008782!; S10-22464).-- Knuth described part of that collection as *moschata*, but assigned another part of Herzog 2013 (L.2008781!) to *fiebrigii*.

= *Hypseocharis pedicularifolia* R. Knuth -- Bot. Jahrb. Syst. 41(3) 173. 1908. Lectotype (here designated):-- BOLIVIA [Dept. Tarija], Prov. Cercado, Puna Patanca, at 3700 m, on the gently sloping edge of the plateau, Calderillo, around 3000 m, on the valley plain between grasses, Fiebrig 2626 (F 218086!; B 10 0279796!), isotypes: K000073728!, MO 2125259!, GH 00043695!.

Type Specimens

= *Hypseocharis pilgeri* R. Knuth -- Bot. Jahrb. Syst. xli. 174 (1908). Holotype:-- PERU [Dept. Lima, Prov. Huarochiri], between Norquinia and Matucana, on stony soil near the river between 2200 and 2700 m, 12.1901, A. Weberbauer 95 (B†).

- *Hypseocharis pimpinellifolia* J. Rémy var. *punicea* Kuntze -- Revis. Gen. Pl. 3[3]: 33. 1898 [28 September 1898]. Petala punicea, Bolivia, 3600 m, Tiraque, O. Kuntze? (B†).-- Kuntze gives only the locality, not the collector. Since he describes both his own collections as various collections from colleagues in this treatise, it is uncertain whose collection the name was based on.

Diagnosis:

Acaulescent rosette herb. **Root tuber** 5–40 cm long and up to 7 cm thick, **leaves** narrowly oblong in outline, (5–)10–20 cm long, lamina 1–13 × 0.5–4.0 cm pinnate, bipinnate or bipinnate with ternate leaflets. **Petiole** 0.2–4.7 cm long, pubescent (rare glabrous). **Leaflets** up to 26, ovate or elliptical, leaflets subsessile, alternate or subopposite, margins dentocrenate (rarely entire), deeply pinnatisect to pinnate with 3–4 incisions on each side, usually deeply pinnatifid or pinnate into narrowly oblong-acuminate lobules or ovate-acuminate leaflets, terminal leaflet deeply dissected, not clearly set off from rachis. Lateral leaflets 0.3 × 0.3 to 2 × 1 cm, obovate or more commonly elliptic in outline, apex dentate, 3-dentate (rarely 2 or 5-dentate) or entire; terminal leaflet 0.4 × 0.2–2.4 × 1.2 cm, obovate, apex dentate or 3-dentate (rare 2-dentate), slightly larger than lateral leaflets,

usually lobed. **Pedicels** (5–) 10–20 cm, pubescent, with 1, more rarely 2–5 (–8) flowers. **Petals** subcircular, obovate or obtiangular, 1–2 × 1–2 cm, red, orange, white or yellow. **Stamens** 15, dorsifixed, with filaments 0.3–1.0 cm long. **Ovary** pubescent with two type of hairs, simple hairs on the style, glandular and/or simple hairs on the ovary. **Fruit** a ventricidal capsule, locules with (1–) 2–3 seeds per carpel (Figure 3).

Hypseocharis tridentata Griseb., Nachr. Königl. Ges. Wiss. Georg-August-Univ. 20: 495. 1877. Holotype:— ARGENTINA [Salta], Los Potreros at the foothills of Nevado

del Castillo, *Hieronymus & Lorentz* 131 (GOET009182!, isotype: CORD00002965!).

Diagnosis:

Acaulescent rosette herb. **Root tuber** 4–6 cm long and 2–3.5 cm thick, **leaves** 1.2–1.9 cm long, 0.5–0.9 cm width, pinnate. **Petiole** 0.5–1.5 cm long, glabrate or pubescent with dilated base, margin almost membranous. **Leaflets** 11–17, entire, alternate or subopposite, sessile, lateral one 0.5–1.4 cm long, oblong or elliptic, terminal one larger than lateral ones, terminal leaflets 0.7–1.8 cm long, ovate, entire or with obtuse three dentate apex or more common with a middle teeth or mucron. **Pedicels** 6 cm long, 1-flowered. **Petals** 0.5–0.8 cm in diameter, caducifolious, white. **Stamens** 5 in a cycle, opposite to the petals. **Ovary** densely glandular. **Fruit** a schizocarp, with 5 dehiscent mericarps, 1-pauciseminales (Figure 4).

Specimens seen:

BOLIVIA. Depto. **Cochabamba**, Prov. Ayopaya, 3270 m, 11.04.1989, R. Baar 256 (LPB). Morochata, rocky slope with low dense grassland with signs of fire, 3809 m, 17° 13' 45.9" S, 66° 26' 33" W, 15.03.2020, *Miranda G.* 61. (4 × BOLV). **ARGENTINA.** Prov. **Jujuy**. 13 km N of Abra Pampa on road to la Quiaca, 3500 m, 24.01.1982, *Willian R. Anderson* 12352 (P). Depto. Agradecimientos / Acknowledgments:

We thank the herbaria LPB and USM for access to their collections. We are very grateful with Gustavo Miranda for his help collecting and measuring *H. tridentata* individuals. Collections of *Hypseocharis "pilgeri"* by the last author were realized based on the collection permit No. 094-2018-MINAGRI-SERFOR/DGGSPFFS thankfully granted by the Servicio Nacional Forestal y de Fauna Silvestre 01 March 2018.

Conflict de intereses / Competing interests:

The authors declare no conflict of interest.

Rol de los autores / Authors Roles:

SLG and SAC collected data and performed the statistical analyses. MW studied the *Hypseocharis pilgeri* population in the field and described the specimens from Peru. TO helped with the methodology to measure specimens in LPB in Bolivia. SLG lead the writing of the manuscript and all authors contributed to the final version of the manuscript.

Fuentes de financiamiento / Funding:

The authors declare, this work not received specific funding.

Aspectos éticos / legales; Ethics / legal:

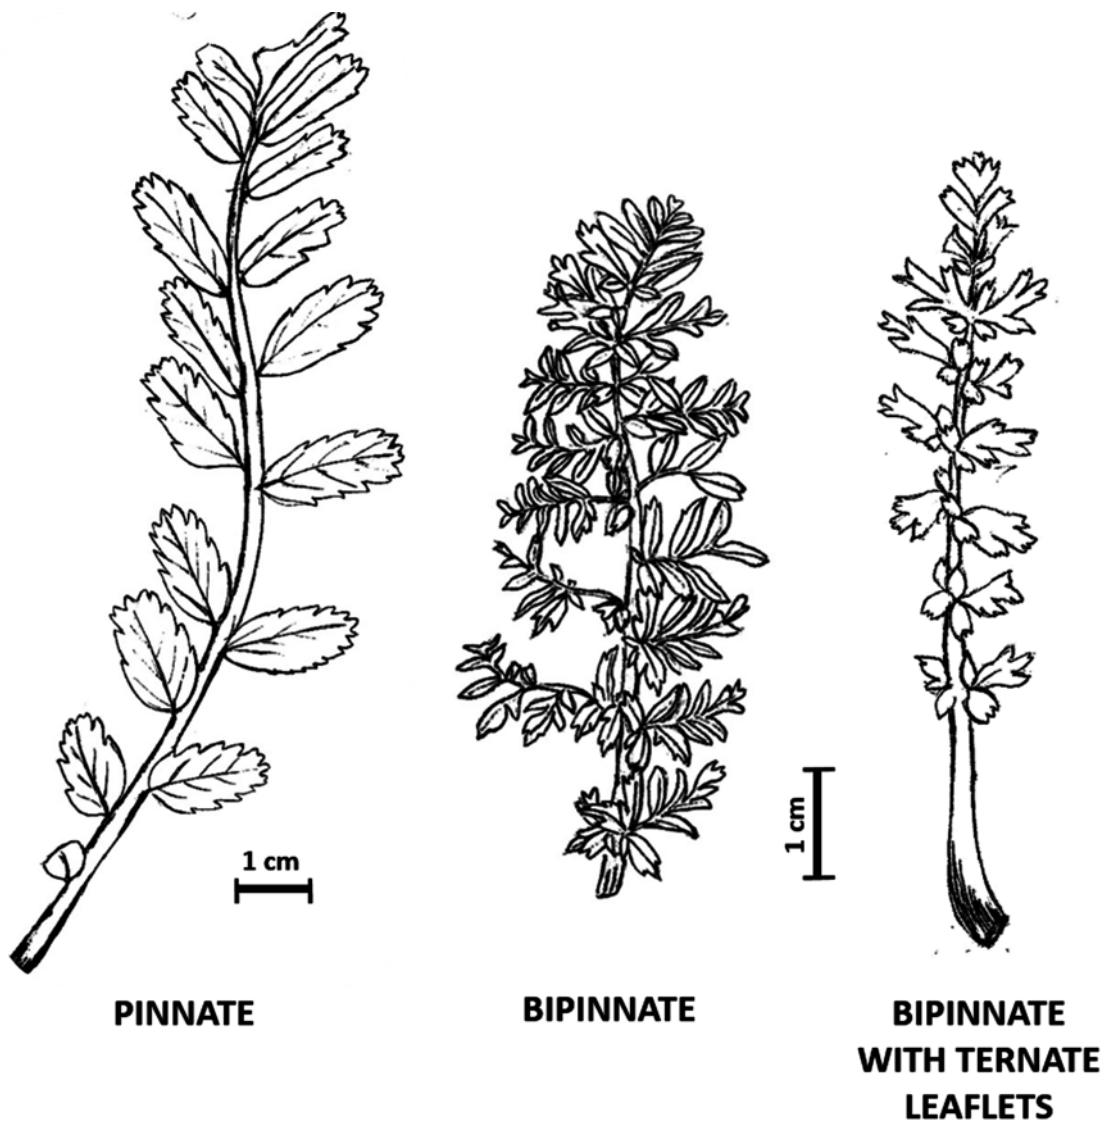

This work did not incur any ethical or legal problems. Collection permit No. 094-2018-MINAGRI-SERFOR/DGGSPFFS.

Supplement - Table A1. Morphometry of vegetative and reproductive characters of 24 specimens of *Hypseocharis* occurring in Bolivia. Trichomes in the ovary: Simple [1], Glandular [2] or both [3]; Type of fruit: Capsule with loculicidal dehiscence [1], dehiscent schizocarp [0].
