#### Abstract

We describe a new species of the cricetid rodent *Thomasomys* (Sigmodontinae) of the "aureus" group based on four specimens collected from Carmen de la Frontera, Piura Department, Peru. This new species has a very long and white tail, very long mystacial vibrissae that extend posteriorly beyond the pinnae, and a distinctive cranial and dental morphology that differ from any other known species of *Thomasomys*. It is also one of the largest species of *Thomasomys*, exceeded in size only by *T. apeco*. A phylogenetic analysis using sequences of *Cytb* recovered this species within a non-monophyletic "aureus" group with a genetic distance between 5.47% (with *T. auricularis*) to 10.17% (with *Thomasomys* sp. 1). In addition to this finding, the phylogenetic position of *T. apeco*, *T. praetor*, and *T. pyrrhonotus* are presented for the first time, prompting a discussion on the nature of the "aureus" group.

#### Resumen

Describimos una nueva especie de roedor cricétido *Thomasomys* (Sigmodontinae) del grupo "aureus" a partir de cuatro especímenes colectados en Carmen de la Frontera, en el departamento de Piura, Perú. Esta nueva especie tiene una cola muy larga y blanca, vibrirasas mistaciales muy largas que sobrepasan ampliamente el pabellón auricular y una morfología craneal y dental distintiva que difiere de cualquier otra especie conocida de *Thomasomys*. También es una de las especies de *Thomasomys* más grandes, superado en tamaño solo por *T. apeco*. Un análisis filogenético recuperó esta especie dentro de un grupo "aureus" no monofilético con una distancia genética entre 5.47% (con *T. auricularis*) y 10.17% (con *Thomasomys* sp. 1). Además, se presenta por primera vez la posición filogenética de *T. apeco*, *T. praetor* y *T. pyrrhonotus*, lo que suscita una discusión sobre la naturaleza del grupo "aureus".

## Introduction

The genus *Thomasomys* Coues, 1884 is one of the most specious genera of the subfamily Sigmodontinae comprising 46 recognized species (Pacheco 2015, Brito et al. 2019, Brito et al. 2021); however, morphological and molecular evidence suggests that diversity is underestimated (Pacheco 2003, 2015, Lee et al. 2015, Brito et al. 2019). *Thomasomys* is endemic to South America in tropical and subtropical habitats and distributed along the Andes in paramo, premontane, and montane forests from northern Venezuela to southern Bolivia, including isolated ranges such as the Serranía de la Macarena in Colombia, at an elevational range of about 1200 m to above 4500 m (Pacheco 2015); and isolated cordilleras like El Condor and Kutukú, in Ecuador (Brito et al. 2021).

The taxonomy of *Thomasomys* has not changed much since the last century. In the last twenty years, four new species were described, *T. onkiro* Luna and Pacheco, 2002 known only from the type locality in southern Peru; *T. ucucha* Voss, 2003 from the Cordillera Oriental at northern Ecuador; *T. andersoni* Salazar-Bravo and Yates, 2007 from eastern slopes of the Bolivian Andes; and *T. salazari* Brito, Tinoco, Curay, Vargas, Reyes-Puig, Romero and Pardiñas, 2019 from Ecuador. At the morphological level, seven informal species groups have been defined (Pacheco 2015), of which the "aureus" group includes mainly medium and the larger rodents in the genus (head and body length: 135–238 mm) distributed throughout the montane forests from Venezuela and Colombia to southeastern Bolivia. Pacheco in 2015, presented several morphological traits to differentiate members of this group, such as long and soft dorsal pelage generally brown-reddish; hypothenar and thenar pad of pes level or overlapping; long digit I of pes; very long digit V; genal 1 vibrissae present; very long mystacial vibrissae; and the moderately counter-shaded body pelage pattern; narrow and convergent interorbital region, not beaded; a large and long postglenoid foramen; molar-bearing portion of the maxillae rectangular; the anteroloph labially and posteriorly oriented; anteroloph in M1 labially and posteriorly oriented; M1 paraloph oriented backward to the mesoloph; the molar hypoflexus broad; and lower molars with a distinct anteromedian flexid and broad and curved posteroflexids. However, the "aureus" group was not yet tested by other sets of characters. At the molecular level, this group was represented by few species (e.g., Salazar-Bravo & Yates 2007a, Lee et al. 2015, 2018a, Brito et al. 2019).

Pacheco et al. (2009) recognized eighteen species of *Thomasomys* for Peru, of which five correspond to the "aureus" group: *T. apeco* Leo and Gardner, 1993, *T. aureus* (Tomes, 1860), *T. praetor* (Thomas, 1900), *T. pyrrhonotus* Thomas, 1886, and *T. rosalinda* Thomas and St. Leger, 1926. Pacheco (2003) also suggested one undescribed species (*Thomasomys* sp. 1) from southern Peru and Bolivia and another from southern Bolivia (*Thomasomys* sp. 2). Recently Brito et al. (2019) recovered two distinct clades in "aureus" group, using sequences of the cytochrome gene, one clade containing *T. aureus*, *T. au-*

*ricularis* Anthony, 1923, and three undescribed species from Ecuador and Bolivia, and another clade containing *T. aureus* from Cusco, Peru (TU03540) close to *T. ladewi* Anthony, 1926; but their representatives of the "aureus" group were very limited. Recently, Brito et al. (2021) described one of the Ecuadorean undescribed species, suggested that *T. aureus* is a complex species, and recovered different topologies for the "aureus" group.

As part of an ongoing study on the taxonomy and biogeography of small mammals from the Peruvian Andes, we reviewed specimens of *Thomasomys* of the Museo de Historia Natural, Universidad Nacional Mayor de San Marcos and found some specimens of *Thomasomys* sp. from northern Peru, Piura Department, with large body-size, long white tail, and very long mystacial vibrissae. These characteristics indicate this form differed strikingly from any other congeneric species. This finding prompted further comparisons with members of the "aureus" group from Peru and Ecuador to test its distinctiveness. In this work, *Thomasomys* sp. nov. of the "aureus" group is described based on a combined approach using morphological and molecular techniques. Our results also allow us to discuss the nature of the "aureus" group.

## Material and methods

**Specimens examined.** *Thomasomys* sp. nov. was represented by four specimens collected in Carmen de la Frontera, Huancabamba Province, Piura Department. For comparative purposes, we included three specimens of *T. apeco*, 12 of *T. aureus* sensu stricto, eight of *T. praetor*, four of *T. pyrrhonotus*, and eight of *Thomasomys* sp. 1 sensu Pacheco (2003). Specimens are housed in the Museo de Historia Natural, Universidad Nacional Mayor de San Marcos (MUSM, Lima) and the American Museum of Natural History (AMNH, New York). Localities are mapped and listed in Figure 1 and Appendix 1, respectively.

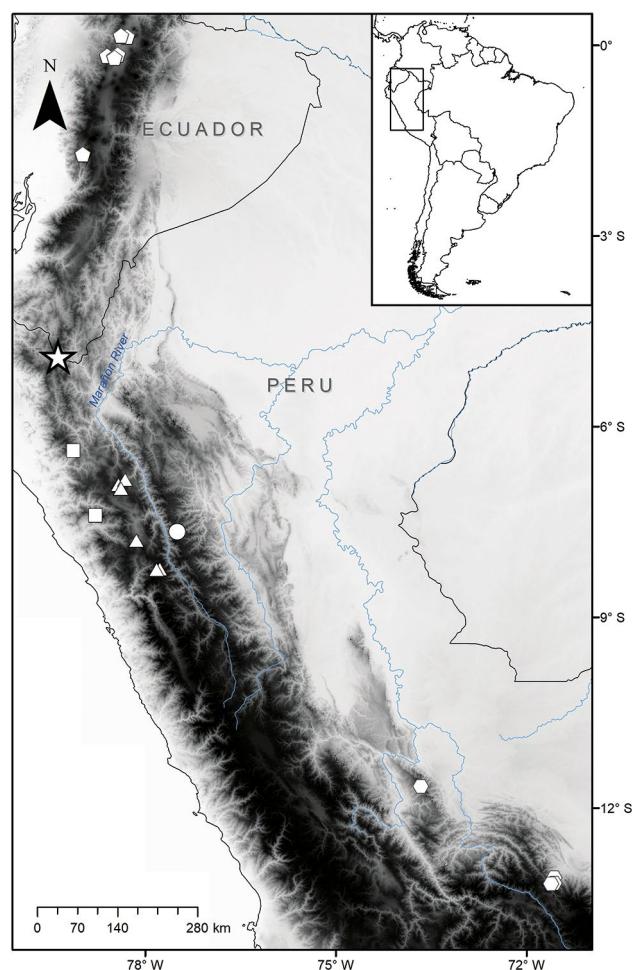

**Morphological methods.** Terminology and definitions employed followed Carleton and Musser (1989) and Voss (1988) for general features, Reig (1977) and Carleton and Musser (1989) for teeth morphology nomenclature, and Pacheco (2003, 2015) for anatomical features of Thomasomyini. Description of fur coloration follows Smith (1975). External measurements (TL: total length, T: tail length, F: hindfoot length, E: ear length) and weight (W) were transcribed from specimen labels. External measurements were taken in millimeters (mm) and mass in grams (g). All cranial and mandibular variables were measured using a dial caliper (error:  $\pm 0.1$  mm). We took 21 measurements following Luna & Pacheco (2002):

- Greatest length of skull (GLS), measured from the tip of the nasals to the posterior margin of occiput.
- Condyloincisor length (CIL), distance from the greater curvature of an upper incisor to the articular surface of the occipital condyle on the same side.
- Condylomolar length (CML), distance from the anterior edge of the first upper molar to the articular surface of the occipital condyle on the same side.

- Length of orbital fossa (LOF), greatest distance of the orbital fossa inside the maxillary and squamosal roots of the zygomatic arch.
- Length of nasals (LN), the greatest length of either nasal bone.
- Diastema length (LD), measured from the crown of the first upper molar to the exposed lesser curvature of the upper incisor on the same side.
- Length of incisive foramina (LIF), distance from the anterior to the posterior edge of one incisive foramen.
- Length of maxillary toothrow (LM), occlusal length of the upper molar row.
- Breadth of incisive foramina (BIF), the greatest distance across the incisive foramina.
- Breadth of rostrum (BR), the least breadth between the anteroventral edges of the zygomatic plates.
- Breadth of palatal bridge (BPB), measured between the protocones of first maxillary molars.
- Breadth of first upper molar (BM1), measured across the protocone-paracone cusp pair of the first upper molar.
- Breadth of nasals (BN), the greatest distance across both nasal bones.
- Least interorbital breadth (LIB), the least interorbital breadth.
- Zygomatic breadth (ZB), the greatest distance across the zygomatic arches.
- Rostral length (RL), from zygomatic notch to the tip of the nasal bone.
- Braincase breadth (BB), measured immediately posterodorsal to the squamosal roots of the zygomatic arches.
- Breadth of zygomatic plate (BZP), the distance between the anterior and posterior edges of the zygomatic plate.
- Depth of incisor (DI), distance between greater and lesser curvature of the upper incisor.
- Height of braincase (HBC), distance from the top of the braincase to the ventral surface of the basisphenoid and basioccipital bones.
- Mesopterygoid fossa breadth (MFB), greater width of the fossa.
- Length of mandibular toothrow (MN), occlusal length of the lower molar row.

Differences in proportions of the skull measures were illustrated by a ratio diagram to show the proportional relationships among the analyzed taxa, following Musser (1970). Values of the *Thomasomys* sp. nov. were used as the midpoint of the standard respect the other species, large measurements than the standard are represented by positive values, those smaller by negative values. For this analysis, we used R (R Development Core Team) with the interface Rstudio 1.2.5001 (RStudio Team 2020) and the “broom” (Robinson et al. 2021), “tidyverse” (Wickham 2019), “readr” (Wickham & Hester 2020), “dplyr” (Wickham et al. 2021), and “scales” (Wickham & Seidel 2020)

packages. Statistic methods were not performed because of the small sample size of cleaned skulls of *Thomasomys* sp. nov. ( $n = 2$ ). For comparative purposes, we added measurements of *T. pardignasi* from Brito et al. (2021).

**Figure 1.** Map showing the collecting localities of *Thomasomys antoniobracci* sp. nov. (star), *T. apeco* (circle), *T. aureus* (pentagons), *T. praetor* (triangles), *T. pyrrhonotus* (squares), and *Thomasomys* sp. 1 (hexagons). Localities are listed in Appendix 1.

**DNA extraction, amplification, and sequencing.** We isolated whole DNA from dry skins of two museum specimens of *Thomasomys* sp. nov. from Piura using the Vivantis extraction kit (Vivantis Technologies, Selangor Darul Ehsan, Malaysia). Also, we isolated DNA from liver or muscle samples preserved in 90% ethanol from two specimens of *Thomasomys* sp. 1, three of *T. apeco*, three of *T. praetor*, and three of *T. pyrrhonotus*. We amplified mitochondrial cytochrome b (*Cytb*) using the primers MVZ05 and MVZ16 (Smith & Patton 1993). PCR products were sequenced by Macrogen (Macrogen Inc., Korea). We checked the sequences using CodonCode Aligner 6.0.2 (CodonCode Corporation, Dedham, USA) and deposited them in Genbank.

**Phylogenetic analysis.** We reconstructed the phylogeny, including the obtained sequences and others downloaded from Genbank from prior publications. We used *Sigmodon hispidus*, *Abrothrix olivaceus*, *Andinomys edax*, *Phyllotis magister*, *Auliscomys micropus*, *Wiedomys pyrrhor-*

*hinus*, *Oecomys bicolor*, *Microryzomys minutus*, *Oxymycterus rufus*, *Akodon boliviensis*, *Rhagomys longilingua*, *Rhipidomys latimanus*, *Rhipidomys mastacalis*, *Chilomys instans*, and species of other *Thomasomys*'s groups (except "aureus" group) as the outgroup, and *Thomasomys* sp. from Piura and species of "aureus" group as the ingroup. All sequences used are listed in Appendix 2. Sequences were aligned by Clustal in MEGA 7.0.14 (Kumar et al. 2016). Substitution model TrN+I+G was selected with jModelTest 2.1.7 (Darriba et al. 2012) by AIC using the "propose model" routine. We performed Maximum Likelihood (ML) and Bayesian inference (BI) methods to reconstruct the phylogenetic relationships of the "aureus" group. The ML analysis was performed by 10000 non-parametric bootstrap replicates to find the best tree using IQ-TREE (Nguyen et al. 2015). Bootstrap values were used as a branch support measure. For the BI analysis, two independent runs were performed with four Markov chains and 10 million iterations; the trees were sampled every 1000 generations, with the first 25 % samples from the cold chain (relburnin = yes and burninfrac = 0.25) discarded by burn-in (Ronquist et al. 2009). This procedure was performed using MrBayes 3.2 (Ronquist et al. 2012) using the GTR+I+G model. Phylogenetic trees were edited in iTOL (Letunic & Bork 2016). Convergence to stable values was checked using Tracer v1.7 (Rambaut et al. 2018) to obtain effective sample sizes (ESS) greater than 200 for all parameters. Finally, uncorrected genetic distances were estimated using the p-distances with 10000 bootstraps replicates from the aligned sequences matrix using Mega 7.0.14.

## Results

**Comparisons.** *Thomasomys* sp. nov. is readily separated from any other species of *Thomasomys* by absolute size (see Table 1) and external and craniodental traits. We provide comparisons with some species of the "aureus" group, which could be potentially sympatric.

Compared to *Thomasomys apeco*, *Thomasomys* sp. nov. has ochraceous-tawny dorsal fur versus raw sienna to ochraceous-tawny; dorsal band is present; tail is entirely whitish versus whitish only in the distal half in *T. apeco*; mystacial vibrissae are conspicuously longer than ears while in *T. apeco* these vibrissae are only slightly longer; metatarsal patch is present (versus absent); ungual tufts are more abundant and longer; hairs on the rump are less dense and shorter (13.00 mm versus 19.30 mm) (Table 2, Figs. 2 and 3). Cranially, rostrum is narrower; nasals are narrower, tapering with anterior margin angular (versus spoon-like with anterior margin rounded); nasals are longer extending beyond the maxillo-fronto-lacrimal (MFL) joint (versus short, anterior to MFL joint); lacrimals are larger; petrosal bone is perforated (versus no perforated); hamular process is straight (versus curved); palatal process is smaller; auditory bullae is moderately inflated (versus no inflated); foramen ovale is larger; stapedial spine is longer; coronoid process is triangular-shaped while in *T. apeco* is sigmoid-shaped; sigmoid notch is angular while in *T. apeco* is rounded; M1 protoloph is present (Table 2, Figs. 4 and 5).

Compared to *Thomasomys aureus* s.s., *Thomasomys* sp. nov. has ochraceous-tawny dorsal fur versus grizzled golden-brown; dorsal band is present; hairs on the hindfeet are dark brown versus whitish in *T. aureus*; tail is whitish while in *T. aureus* is darkish; ventral is yellowish less intense; metatarsal patch is present (Table 2, Figs. 2 and 3). Cranially, nasals are long, posterior to MFL joint (versus short, anterior to MFL joint); palatal process is small while in *T. aureus* s.s. it can be absent or small; sphenopalatine vacuities are slits while in *T. aureus* they can be closed or slits; stapedial spine is longer; coronoid process is triangular-shaped (versus sigmoid-shaped); sigmoid notch is angular (versus rounded); capsular process have more a distinct ridge and sulcus (Table 2).

Compared to *Thomasomys praetor*, *Thomasomys* sp. nov. has ochraceous-tawny dorsal fur versus olivaceous grayish; dorsal band is present; hairs on the hindfeet are dark brown (versus whitish); tail is whitish while in *T. praetor* is darkish; auricular patch is absent (versus present); mystacial vibrissae pass ears while in *T. praetor* pass ears slightly; tips of the ventral fur color are yellowish (versus whitish); metatarsal patch is present (versus absent); hairs on the rump are longer (13.00 mm versus 10.30 mm); rostrum is narrower (Table 2, Figs. 2 and 3). Cranially, nasals are narrower, tapering (versus spatulated), with anterior margin angular (versus rounded); zygomatic notch is shallower; lacrimals are larger; parietal lateral process is smaller; petrosal bone is perforated (versus no perforated); mesopterygoid fossa is broader and slightly expanded anteriorly (versus narrow and parallel); incisive foramina are longer; palatal process is small (versus absent); sphenopalatine vacuities are narrow slits while in *T. praetor* are a little larger; stapedial spine is longer; coronoid process is triangular-shaped (versus sigmoid-shaped); sigmoid notch is angular (versus rounded); capsular process has distinct ridge and sulcus (versus ridge and weak sulcus); upper molar rows are parallel while in *T. praetor* are divergent; M1 protoloph is present (versus absent); M1 anteromedian flexus is distinct (versus shallow); M1 mesoloph is distinct (versus short and weak) (Table 2, Figs. 4 and 5).

Compared to *Thomasomys pyrrhonotus*, *Thomasomys* sp. nov. has ochraceous-tawny dorsal fur versus rich rufous and olivaceous; dorsal band is present; hairs on the hindfeet are dark brown (versus beige); tail is whitish while in *T. pyrrhonotus* is darkish; mystacial vibrissae pass ears while in *T. pyrrhonotus* slightly pass the ears; tips of the ventral fur are yellowish (versus whitish); metatarsal patch is present while in *T. pyrrhonotus* is variable; hair on the rump is less dense and shorter (13.00 mm versus 11.80 mm) (Table 2, Figs. 2 and 3). Cranially, anterior margin of the nasals is angular (versus rounded); nasals are long, posterior to MFL joint (versus slightly long, at level MFL joint); lacrimals are larger; parietal lateral process is smaller; hamular process is shorter; mesopterygoid fossa is broader and slightly expanded anteriorly (versus parallel); palatal process is small (versus absent); sphenopalatine vacuities are narrow (versus moderate); eustachian tube is

slightly larger (versus short); auditory bullae is less inflated versus notably inflated; stapedial spine is longer; coronoid process is triangular-shaped versus (sigmoid-shaped); sigmoid notch is angular (versus rounded); up-

per molar rows are parallel while in *T. pyrrhonotus* are divergent; upper incisors are slightly opistodont (versus opistodont); M1 protoloph is present (Table 2, Figs. 4 and 5); procingulum is larger.

**Table 1.** Weight (in grams) and measurements (in millimeters) of adult specimens of *Thomasomys antoniobracki* sp. nov. (MUSM 23756, 23757), *T. apeco*, *T. aureus*, *T. pardignasi*, *T. praetor*, *T. pyrrhonotus*, and *Thomasomys* sp. 1 sensu Pacheco (2003). Values of *T. aureus* were taken from Pacheco (2021) and of *T. pardignasi* from Brito et al. (2021). Specimens are listed in Appendix 1. See abbreviations in Material and methods. Values shown above: mean, standard deviation, and sample size in parenthesis; below: minimum and maximum range..

**Table 2.** Morphological differences among *Thomasomys antoniobracki* sp. nov., *T. apeco*, *T. aureus*, *T. praetor*, *T. pyrrhonotus*, and *Thomasomys* sp. 1 sensu Pacheco (2003).

Characters	<i>T. antoniobracki</i> sp. nov.	<i>T. apeco</i>	<i>T. aureus</i>	<i>T. praetor</i>	<i>T. pyrrhonotus</i>	<i>Thomasomys</i> sp. 1
Dorsal fur color	Ochraceous-tawny	Raw sienna to ochraceous-tawny	Grizzled golden- brown	Olivaceous grayish	Rich rufous and olivaceous	Rich rufous
Dorsal band	Present	Absent	Absent	Absent	Absent	Present
Hairs on the hindfeet	Dark brown	Dark brown	Whitish	Whitish	Beige	Beige
Color tail pattern (along)	Entirely whitish	Whitish distal half and darkish basal half	Entirely darkish	Entirely darkish	Entirely darkish	Entirely darkish
Auricular patch	Absent	Absent	Absent	Present	Absent	Absent
Mystacial vibrissae	Pass ears	Pass ears slightly	Pass ears	Pass ears slightly	Pass ears slightly	Pass ears slightly
Ventral fur color (tips)	Yellowish	Yellowish	Yellowish, almost golden	Whitish	Whitish	Yellowish
Metatarsal patch	Present	Absent	Absent	Absent	Sometimes present	Present
Ungual pes tuft	Abundant and long	Scarce and short	Abundant and long	Abundant and long	Abundant and long	Scarce and long
Hair on the rump	No dense and short (13.00 mm)	Dense and large (19.30 mm)	–	No dense and short (10.30 mm)	Dense and short (11.80 mm)	No dense and short (10.50 mm)
Rostrum	Narrow	Broad	Narrow	Broad	Narrow	Narrow
Nasal shape	Narrow, tapering, anterior margin angular	Spoon-like, anterior- margin rounded	Narrow, tapering, anterior margin angular	Broad, spatulated, anterior margin rounded	Narrow, tapering, anterior margin rounded	Narrow, tapering, anterior margin rounded
Nasal length	Long, posterior to MFL joint	Short, anterior to MFL joint	Short, anterior to MFL joint	Long, posterior to MFL joint	Level MFL joint	Level MFL joint
Zygomatic notch	Shallow	Shallow	Shallow	Deep	Shallow	Shallow
Lacrimal	Large	Small	Large	Small	Small	Large
Parietal lateral process	Small	Small	Small	Large, broad	Large, subtriangular	Small
Petrosal bone	Perforated	No perforated	Perforated	No perforated	Perforated	Perforated
Hamular process	Long, narrow, straight	Long, curved	Long, narrow, straight	Long, narrow, straight	Very long and narrow, straight	Long, narrow, straight
Incisive foramina	Long	Long	Long	Moderate	Long	Long
Mesopterygoid fossa	Broad, slightly ex- panded anteriorly	Broad, slightly ex- panded anteriorly	Broad, slightly ex- panded anteriorly	Narrow, parallel	Narrow, parallel	Broad, slightly ex- panded anteriorly
Palatal process	Small	Distinct	Absent or small	Absent	Absent	Small
Sphenopalatine vacuities	Slits	Slits	Closed or slit	Moderate	Moderate	Closed
Foramen ovale	Large	Small	Large	Large	Large	Large
Eustachian tube	Medium	Medium	Medium	Medium	Short	Medium
Auditive bullae	Moderately in- flated	No inflated	Moderately in- flated	Moderately in- flated	Largely inflated	No inflated
Stapedial spine	Long and narrow	Short	Short	Short	Short	Short
Coronoid process	Triangular-shaped	Sigmoid-shaped	Sigmoid-shaped	Sigmoid-shaped	Sigmoid-shaped	Sigmoid-shaped
Sigmoid notch	Angular	Rounded	Rounded	Rounded	Rounded	Rounded
Capsular process	Distinct ridge and sulcus	Distinct ridge and sulcus	Ridge and weak sulcus	Ridge and weak sulcus	Distinct ridge and sulcus	Ridge and weak sulcus
Upper molar rows	Parallel	Parallel	Parallel	Divergent	Divergent	Parallel
Upper Incisors	Slightly opistho- dont	Slightly opistho- dont	Slightly opistho- dont	Slightly opistho- dont	Opistodont	Slightly opistho- dont
M1 protoloph	Present	Absent	–	Absent	Absent	Absent
M1 anteromedian flexus	Distinct	Distinct	–	Shallow	Distinct	Distinct
M1 mesoloph	Distinct	Distinct	–	Short, weak	Distinct	Distinct
m1 procingulum	Large	Large	–	Large	Small	Small

**Figure 2.** Dorsal views of the skin of *Thomasomys antoniobracki* sp. nov. (A: MUSM 23757, holotype), *T. apeco* (B: MUSM 7199), *T. aureus* (C: MSB 70707), *T. praetor* (D: MUSM 38498), *T. pyrrhonotus* (E: MUSM 46761), and *Thomasomys* sp. 1 (F: MUSM 9347). Scale: 50 mm.

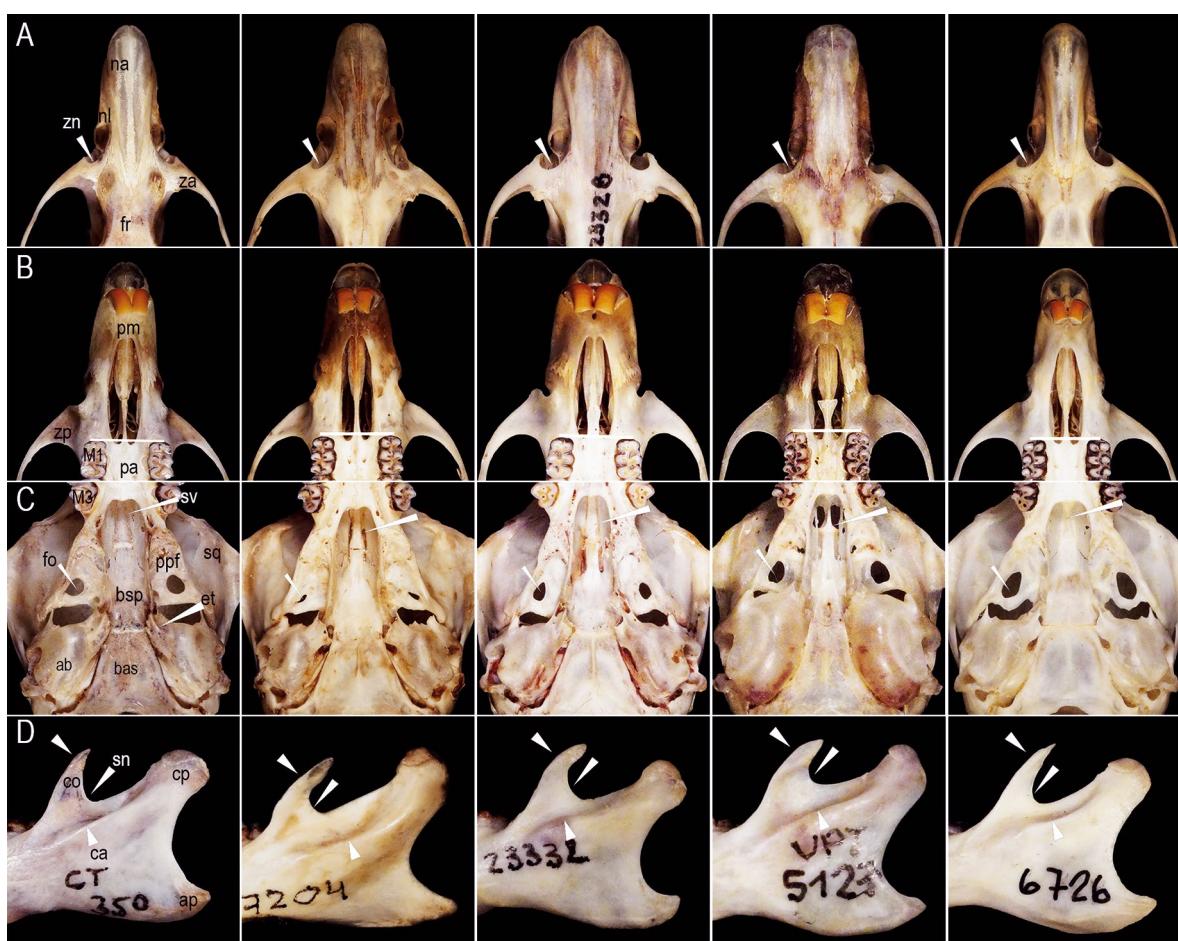

**Figure 3.** Ventral views of the skin of *Thomasomys antoniobracki* sp. nov. (A: MUSM 23757, holotype), *T. apeco* (B: MUSM 7199), *T. aureus* (C: MSB 70707), *T. praetor* (D: MUSM 38498), *T. pyrrhonotus* (E: MUSM 46761), and *Thomasomys* sp. 1 (F: MUSM 9347). Scale: 50 mm.

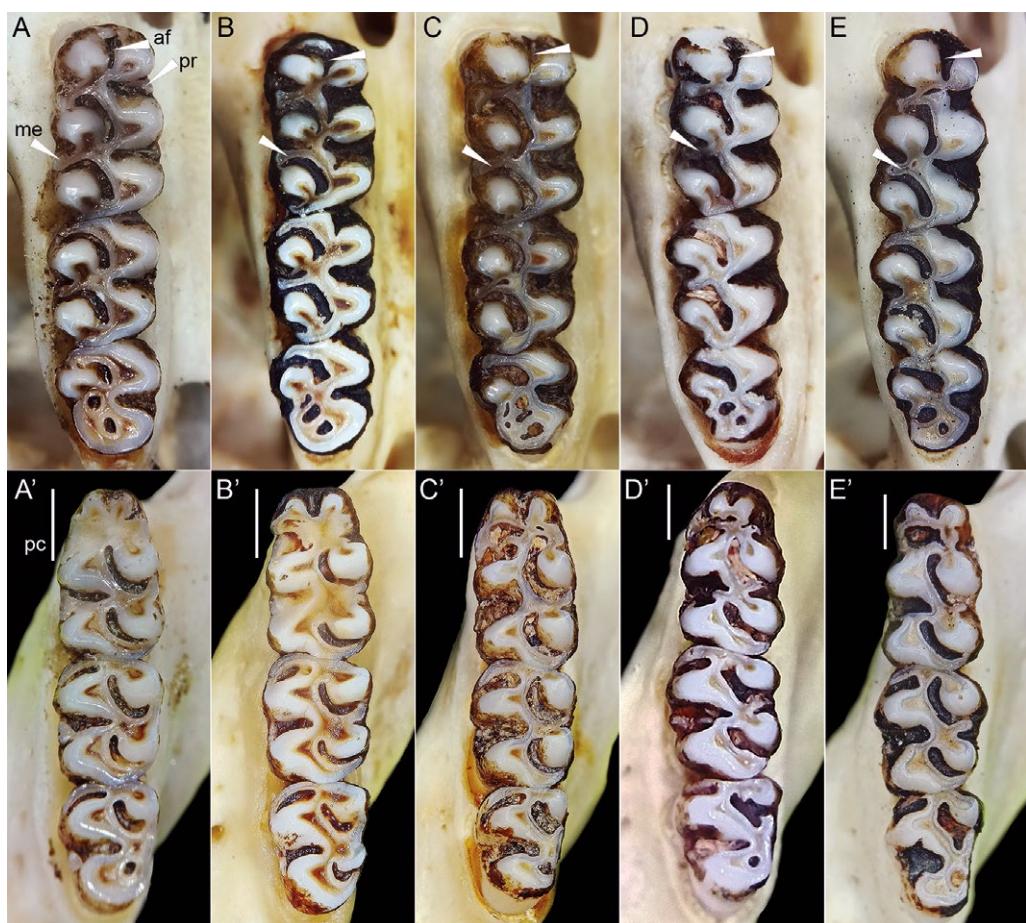

Compared to *Thomasomys* sp. 1 sensu Pacheco (2003), *Thomasomys* sp. nov. has ochraceous-tawny dorsal fur versus rich rufous; hairs on the hindfeet are dark brown (versus beige); tail is whitish versus darkish in *Thomasomys* sp. 1; mystacial vibrissae are distinctly longer than ears while in *Thomasomys* sp. 1 are slightly longer; ungual tuft on the pes is more abundant; hairs on the rump are longer (13.00 mm versus 10.50 mm) (Table 2, Figs. 2 and 3). Cranially, anterior margin of the nasal is angular versus rounded in *Thomasomys* sp. 1; nasals are long, posterior to MFL joint (versus slightly long, at level MFL joint); sphenopalatine vacuities are narrow versus closed; auditory bullae is moderately inflated (versus no inflated); stapedial spine is longer; coronoid process is triangular-shaped while in *Thomasomys* sp. 1 is sigmoid-shaped; sigmoid notch is angular in *T. aureus* is rounded; capsular process has distinct ridge and sulcus (versus ridge and weak sulcus); M1 protoloph is present; procinculum is larger (Table 2, Figs. 4 and 5).

*Thomasomys* sp. nov. is smaller than *T. apeco* in all variables, but is larger than *T. aureus* s.s., *T. pyrrhonotus*, and *Thomasomys* sp. 1 in all variables. Compared with *T. praeator*, *Thomasomys* sp. nov. is larger in most variables, except in BN and DI (Table 1, Fig. 6). Among analyzed species, *T. pardignasi* and *T. pyrrhonotus* were the smallest species.

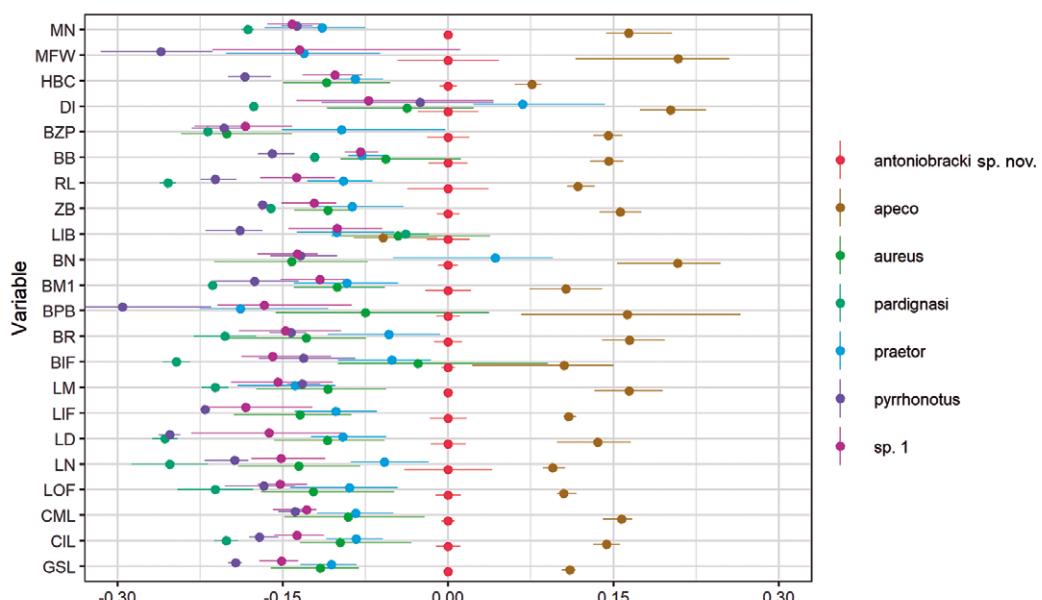

**Molecular evidence.** The phylogenetic analysis was based on molecular data of 81 sequences of *Cytb* gene of 801 bp of which 425 were constant, 321 were parsimony informative, and 55 were singletons. The ML and BI analysis of the *Cytb* matrix failed to recover a monophyletic "aureus" group (Fig. 7). *Thomasomys apeco* and *Thomasomys* sp. 1, members of "aureus" group (following Pacheco (2015)) form a monophyletic group (bs = 86, pp = 0.9); however, this clade was recovered as sister of *Thomasomys notatus* ("notatus" group); and this clade as the sister group (bs = 79) of the clade *T. baeops* + *T. taczanowskii* ("baeops" group) (bs = 100, pp = 1).

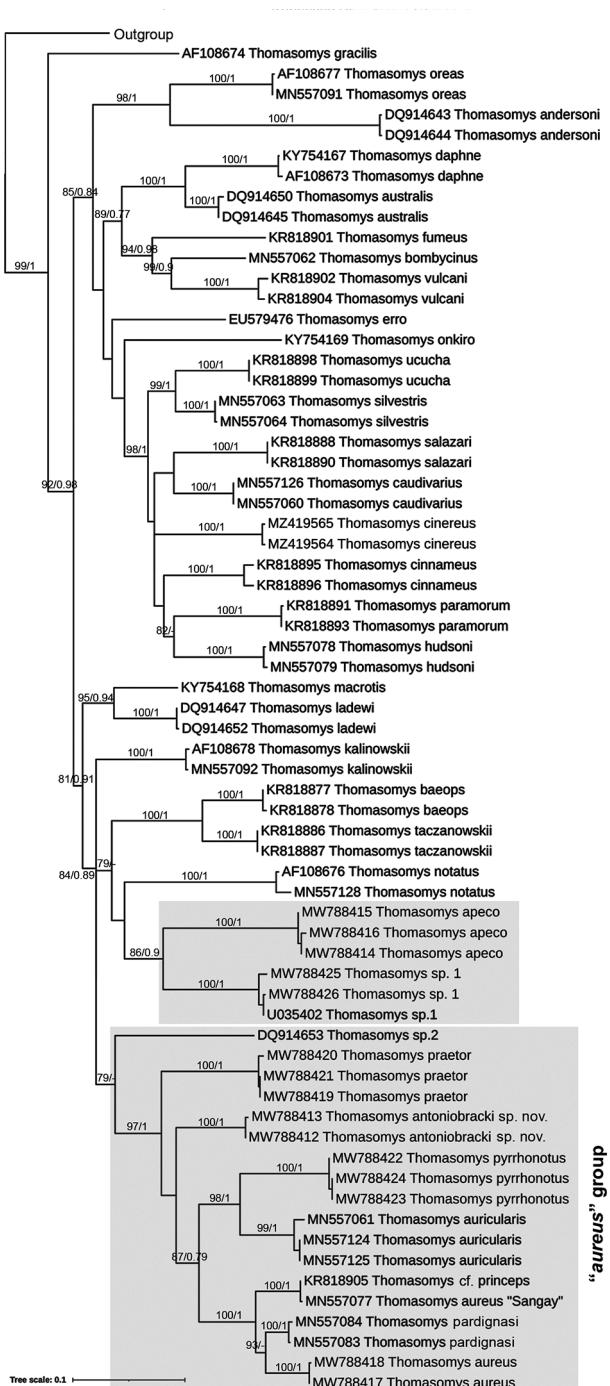

**Figure 4.** Morphological comparisons (from left to right) among *Thomasomys antoniobracci* sp. nov. (MUSM 23757, holotype), *T. apeco* (MUSM 7204), *T. praeator* (MUSM 23328), *T. pyrrhonotus* (MUSM 52410), and *Thomasomys* sp. 1 (MUSM 6726). Characters shown in *T. antoniobracci* sp. nov.: A) zygomatic notch shallow and the narrow rostrum, B) long incisive foramina, C) short palate, sphenopalatine vacuities slits, medium-sized eustachian tube, and moderately inflated auditory bullae, D) triangular-shaped coronoid process slightly short, angular sigmoid notch and distinct ridge and sulcus of the capsular process. Abbreviations: ab, auditory bulla; af, anteromedian flexus; ap, angular process; bas, basioccipital; bsp, basisphenoid; ca, capsular process; co, coronoid process; cp, condylar process; et, eustachian tube; fo, foramen ovale; fr, frontal; M1, first upper molar; M3, third upper molar; me, mesoloph; na, nasal; nl, nasolacrimal foramen; pa, palatal; pm, premaxillary; ppf, parapterygoid fossa; pr, protoloph; sn, sigmoid notch; sq, squamosal; sv, sphenopalatal vacuities; za, zygomatic arch; zn, zygomatic notch; zp, zygomatic plate. Not scaled.

**Figure 5.** Comparisons of upper molars (top) and lower molars (bottom) of A) *Thomasomys antoniobracci* sp. nov. (MUSM 23756), B) *T. apeco* (MUSM 7198 [top], MUSM 7204 [bottom]), C) *Thomasomys* sp. 1 (MUSM 9363), D) *T. praetor* (MUSM 40211), and E) *T. pyrrhonotus* (MUSM 40359). See in *Thomasomys antoniobracci* sp. nov. protoloph present in first upper molar, distinct anteromedian flexus and mesoloph in first upper molar. Abbreviations: af, anteromedian flexus; me, mesoloph; pc, procingulum; pr, protoloph. Not scaled.

**Figure 6.** Ratio diagram comparing the mean values for each external and cranial dimension among *T. antoniobracci* sp. nov., *Thomasomys apeco*, *T. aureus* (taken from Pacheco 2021), *T. praetor*, *T. pardignasi* (taken from Brito et al. 2021), *T. pyrrhonotus*, and *Thomasomys* sp. 1. See Materials and Methods for abbreviations.

**Figure 7.** Tree resulting from the maximum-likelihood analysis of species of "aureus" group of *Thomasomys*. Numbers on the branches indicate ML bootstrap values (left of the diagonal) and Bayesian posterior probabilities (right of the diagonal). Sequences are listed in Appendix 2. The "aureus" group is highlighted in gray.

All the other studied species members of "aureus" group were recovered in a monophyletic group with moderate support ( $bs = 79$ ). *Thomasomys* sp. 2. was recovered as sister of the other species. ML and BI topologies were congruent showing *Thomasomys* sp. nov. into a well-supported clade ( $bs = 97$ ,  $pp = 1$ ) containing *T. aureus* s.s., *T. aureus* "Sangay" (MN557077), *T. auricularis*, *T. pardignasi*, *T. praetor*, *T. cf. princeps*, and *T. pyrrhonotus*. The genetic divergence observed between *Thomasomys* sp. nov. and the remaining species of the "aureus" group

range from 5.47 % (with *T. auricularis*) to 10.17 % (with *Thomasomys* sp. 1) (Table 3). Intraspecific distance of *Thomasomys* sp. nov. is  $0.51 \pm 0.29$  %. On the other hand, the genetic distance of *T. aureus* s.s. versus *T. aureus* "Sangay" was  $5.64 \pm 1.19$  %, versus *T. pardignasi* was  $4.49 \pm 1.01$  %, versus *Thomasomys* sp. 1 was  $11.88 \pm 1.67$  %, and versus *Thomasomys* sp. 2 was  $9.74 \pm 1.60$  % (Table 3).

Given the evidence from the morphological, morphometric, and molecular analyses, we recognize that *Thomasomys* sp. nov. from Piura Department as a full species and member of the "aureus" group. Because no name is available for this new taxon, we provide a name and a formal description.

## Taxonomy

ORDER RODENTIA BOWDICH, 1821

FAMILY CRICETIDAE FISCHER, 1817

SUBFAMILY SIGMODONTINAE WAGNER, 1843

TRIBE THOMASOMYINI STEADMAN AND RAY, 1982

### *Thomasomys antoniobracki* sp. nov.

"RATÓN MONTARAZ COLIBLANCO DE ANTONIO BRACK"

**Holotype.** The holotype is an adult female specimen deposited at the Departamento de Mastozoología, Museo de Historia Natural de la Universidad Nacional Mayor de San Marcos (MUSM 23757), collected by Carlos Tello (original field number CT 350) on April 15, 2006, and prepared as skin and cleaned skull, with carcass preserved in ethanol. (Fig. 8).

**Type locality.** Campamento Alto Parramata at 2630 m elevation, in Carmen de la frontera district, Huancabamba province, Piura department, Peru,  $4.89429^\circ$  S,  $79.36761^\circ$  W (Fig. 1).

**Paratypes.** Paratypes include three adult specimens preserved as skull, skin, and carcass (MUSM 23756) and alcoholic specimens (MUSM 23754, 23755) collected in the type locality. Measurements of the holotype and paratype specimens are provided in Table 1.

**Diagnosis.** A large rodent of the genus *Thomasomys* in the "aureus" group (head and body length: 184–188 mm), distinguished from congeners by the following combination of characters: narrow rostrum; narrow nasals, tapering and long extending to the maxillary-frontal-lacrimal intersection or beyond; shallow zygomatic notch; large lacrimals; palate bone narrow with posterior margin leveling about half M3, small palatal process present; mesopterygoid fossa broad, slightly expanded anteriorly; sphenopalatine vacuities present as narrow slits; large oval foramen; auditory bullae moderately inflated; stapedial spine long and narrow; capsular process absent but produced as a swollen ridge with an inner sulcus between the ridge and the sigmoid notch; coronoid process triangular and sigmoid notch angular; upper incisors slightly opistodont; M1 protoloph present; M1 and M3 hypoflexus distinct.

**Table 3.** Uncorrected genetic distances within (In: intraspecific distances) and among (below diagonal: p-distances, above diagonal: standard error) the species of the "aureus" group of *Thomasomys*.

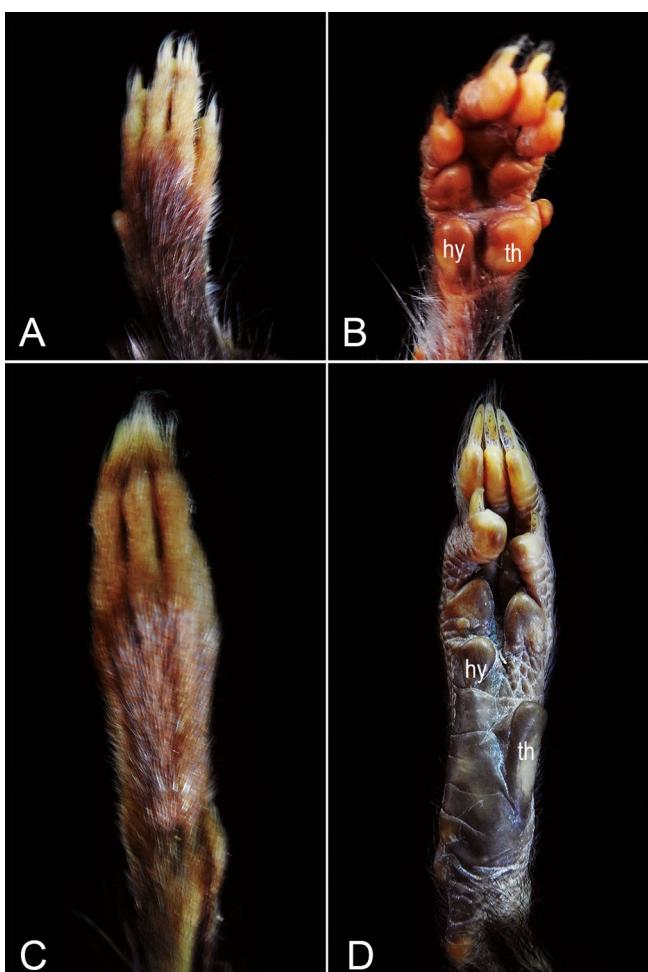

**Figure 8.** Dorsal, ventral, and lateral views of the cranium and lateral view of the mandible of the holotype of *Thomasomys antoniobracki* sp. nov. (MUSM 23757, holotype, age class 3). Scale: 10 mm.

**Description.** Figs. 2, 3, 4, 5, 8, and 9. **Body.** *Thomasomys antoniobracki* sp. nov. exhibits slightly long fur, 12.0 to 14.0 mm on the rump, and not dense; the pelage is soft with a silky texture. The hairs of the dorsal pelage are slate at the base (color 82: blackish neutral gray) and the tips ochraceous-tawny (color 26: clay color, and co-

lor 33: cinnamon brown), and a band dark brown (color 219: sepia color) on the midline, the sides are somewhat more light brown. The dorsum and sides are moderately contrasting with the venter. The ventral pelage is slate at the base (color 83 dark neutral grey) and tips yellowish (color 223D: tawny olive, and color 124: buff). The ears are slightly large (26–30 mm) with a fine dark brown fur (color 219: sepia). The genal, superciliary, submental, interramal, and mystacial vibrissae are present; mystacial vibrissae long extending posteriorly well behind the pinnae when laid back against the head. Fine dark brownish hairs (patch) cover the dorsal surface of the manus and pes. Long, abundant, and whitish ungual tufts cover the claws. The hairs on the feet are blackish. The thenar is larger than the hypothenar and separated from it by a large gap. The plantar surface is squamated. Digit I of pes is the shortest; the claw reaches half the length of phalanx 1 of digit II. Digit V of pes extends to the base of claw of digit IV. The claw of digits II, III, and IV are almost the same size. The tail is monocolored (white dorsally and ventrally), longer than the body and head length. **Skull.** The skull of *Thomasomys antoniobracki* sp. nov. is comparatively large. The rostrum is long and narrow (in dorsal view) and moderately deep at the zygomatic plate level. The nasals are long, tapering backward and extending beyond the maxillary-frontal-lacrimal suture. The anterior border of the nasals is angular and projects beyond the premaxillae and the anterior border of the incisors. Rostral tube absent. The posterior margin of the premaxilla level the zygomatic notch. The bridge of the zygomatic root is high. The zygomatic notch is shallow. The zygomatic plate is broad without spine, free margins straight. The zygoma bend ventrally, but the lowest margin is unusually horizontal, placed just above the molar bridge of teeth. The zygomatic arch is divergent and slightly rounded. The jugal is long and slender. The masseteric tubercle is absent, exhibiting only a visible scar. The maxillary bridge of molars is triangular in ventral view. The lachrymal are slightly large, squarish, and slightly elevated. The interorbital region is extremely narrow, with border squarish and margins slightly diver-

gent. These margins are not projected over the parietal except on the base of the postero-lateral process of the parietal, where almost a line is insinuated. The frontoparietal suture is semi-triangular. The petrosal bone is perforated. The interparietal is large, broad and oval, broad, exposing a small and indented occipito-parietal suture. The lambdoid crest is absent. The carotid circulation has pattern 3 (sensu Voss 1988). The alisphenoid strut is present and robust. The braincase is slightly rounded, the fronto-parietal suture is V-shaped, the squamosal-parietal suture is smooth. The diastema (in lateral view) is slightly flat. The incisive foramina are narrow and long with subparallel margins. The premaxillary portion of the septum is broad and extends half the foramina length, while the maxillary portion of the septum is long and very constricted. The ethmoid foramen is small. The palatal bone is short with a small posterior process. The posterolateral palatal pits are small and placed anterior to the mesopterygoid fossa. The mesopterygoid fossa is broad, slightly expanded anteriorly. The sphenopalatine vacuities are represented as narrow slits. The parapterygoid fossa is triangular and broad with inconspicuous vacuities. The oval foramen is large. The middle lacerate foramen is open, extended anteriorly beyond the bony eustachian tube level; the alisphenoid extends from the anterior edge of tympanic bullae to the sphenopalatine foramen, and the alar fissure is shallow. The optic foramina are large and dorsal to M3. The ectotympanic bullae are elongated and moderately inflated. The ectotympanic ring is closed, although the ectotympanic margin is very narrow and weakly approaches the mastoid. The tegmen tympani overlaps the posterior suspensory process of the squamosal. The bony eustachian tube is slightly long and extend to the posterior margin of the parapterygoid fossae. The stapedial spine is long and slender and reaches the posterior margin of the alisphenoid bone. The postglenoid foramen is narrow and elongated, smaller than the subsquamosal fenestra, and both are separated by a long, straight, and slightly broad hamular process that reaches the mastoid bone to the nuchal crest. The basioccipital is sub triangular. The foramen magnum is slightly rounded. **Mandible.** The coronoid process is triangular-shaped and reaches the condylar process. The sigmoid notch is angular. A distinct capsular process is absent, but the lower incisor roots produce a distinct ridge and sulcus. **Teeth.** The upper incisors are opistodont with yellow-orange enamel on the external surface. The molar rows are parallel. The first upper molar (M1) is large; the procingulum is anteriorly rounded and asymmetrically divided by a deep anteromedian flexus; the anteroloph is long narrow, and oriented labially and posteriorly; anteroflexus is shallow; paraflexus and metaflexus are very deep; mesoloph is slightly narrow, long, and oriented labially and posteriorly; hypoflexus is deep; posteroloph is small; the protoloph is present. The second upper molar (M2) is smaller than M1; anteroloph is long, thin, and reaches the labial surface; protoflexus is small; mesoloph is slightly short and oriented labially and posteriorly; posteroloph is very small. The third upper molar (M3) is smaller than M2; anteroloph is long, slightly broad, and reaches the

labial surface; protoloph is present. The first lower molar (m1) is large; procingulum is symmetrically divided by a deep anteromedian flexid; mesolophid is narrow; hypoflexid is small and perpendicular to the labial surface; posterolophid is long, slightly broad. The second lower molar (m2) is smaller than m1; anterolabial cingulum is long and narrow; mesolophid is slightly long; posterolophid is long and slightly broad. The third lower molar (m3) is smaller than m2; anterolabial cingulum is long and narrow.

**Figure 9.** Dorsal and ventral views of the right manus (A, B) and right pes (C, D) of *Thomasomys antoniobracci* sp. nov. (MUSM 23754). Abbreviations: th, thenar; hy, hypothenar.

**Etymology.** *Thomasomys antoniobracci* sp. nov. is named in honor of Antonio José Brack Egg (Oxapampa, Pasco, June 3, 1940 – Lima, December 30, 2014), a Peruvian professor, ecologist, writer, politician, photographer, TV host, conservationist, science communicator, and researcher in biodiversity and bio-trade development. In 2006, he was appointed president of the Consejo Nacional del Ambiente (CONAM), the main environmental council up to that date in Peru. Then he was appointed as the first Minister of the new Ministry of Environment of Peru between 2008 and 2011. He stood out for his efforts to implement the new ministry and fight against illegal mining in the Peruvian Amazon. Antonio Brack was also professor at various local universities such as

Universidad Nacional Agraria La Molina, Universidad ESAN, Universidad Ricardo Palma, Universidad Nacional de la Amazonía Peruana, Universidad Nacional Mayor de San Marcos, among others. He was the author of outstanding publications on Peruvian biodiversity and received several recognitions that include the Bárbara D'Achille National Environmental Award in 1996, Esteban Campodónico Award in 2004, and the Carlos Ponce del Prado Conservation Award in 2014.

**Distribution.** *Thomasomys antoniobracki* sp. nov. occurs in the montane forest of northern Peru, and it is currently known only from the type locality. The elevational range is from 2620 to 2720 m.

## Discussion

### Remarks on *Thomasomys antoniobracki* sp. nov.

Our results based on morphological and molecular evidence support *Thomasomys antoniobracki* sp. nov. as a valid species, increasing to 47 the valid species of *Thomasomys* (Pacheco 2015, Brito et al. 2019, 2021). Morphologically, *T. antoniobracki* sp. nov. exhibits many fixed autapomorphic traits, such as the whitish tail, long and narrow stapedial spine, slightly short and triangular-shaped coronoid process, angular sigmoid notch, and protoloph present in M1. *T. antoniobracki* sp. nov. is also conspicuously distinct from congeners by its large size (GLS: 45.39 mm), being second only to *T. apeco*, currently the largest living thomasomyine rodent (GLS: 51 mm; Leo L & Gardner 1993). Divergence of the new species respect to another species of the "aureus" group (5.47 % - 10.17 %) fits the threshold of interspecific variation (Baker & Bradley 2006), similar to distances previously found among *Thomasomys* species using *Cytb* (e.g., Salazar-Bravo & Yates 2007, Brito et al. 2019, 2021).

*Thomasomys antoniobracki* sp. nov. is currently considered an endemic species from the montane forest of northern Peru and known only for the type locality. However, it is likely to occur in nearby northern forests Peru and even probably in Ecuador. Although the northern montane forests seem parts of a near-continuous strip, they are presented like relict forests that house several endemic and altitudinal specialists species of flora and fauna, so they have outstanding importance for biodiversity conservation (Young & León 1999, Weigend et al. 2013, Weigend 2013). Other *Thomasomys* species recorded with *T. antoniobracki* sp. nov. are *T. caudivarius* Anthony, 1923, *T. taczanowskii* (Thomas, 1882), and *T. cf. vulcani*. Following the distributional ranges presented by Pacheco (2015) for *Thomasomys* species, *T. antoniobracki* sp. nov. is possibly cohabiting with *T. aureus* and *T. cinereus* (Thomas, 1882).

The type locality of *T. antoniobracki* sp. nov. is not into a protected area, but it is at about 20 km (straight line) to the Santuario Nacional Tabaconas-Namballe, Cajamarca, Peru. This area is important for biodiversity conservation and protects some endangered large mammal species such as the "spectacled bear" *Tremarctos ornatus* and the "mountain tapir" *Tapirus pinchaque* (Mena &

Velazco 2010, Cavalier et al. 2011). Although many studies have been carried out in this area (e.g., Rodríguez G 1995, Mena & Velazco 2010, Mena & Yagui 2019, Mena & Pacheco 2020), the diversity of small mammals is still poorly known. Hopefully, *T. antoniobracki* sp. nov. is likely to occur in SN Tabaconas-Namballe. The type locality is also near the limit with Ecuador at eastern Andes (about 2.4 km). In Peru, this area has not been extensively studied, and there are some mammal species from montane forests occurring near the limit that has not been yet recorded but are present in Ecuador, such as *T. auricularis* or *T. baeops* (Thomas, 1899). In contrast, Ecuador has a better knowledge of its mammal diversity in these montane forests (e.g., Aguirre Mendoza et al. 2017, Lee et al. 2018, Moreno Cárdenas & Novillo-Gonzalez 2020), but in any of these surveys, *T. antoniobracki* sp. nov. has been recorded yet.

### Remarks on species of the "aureus" group

The species diversity of *Thomasomys* is far from being known. Remarkably, the "aureus" group, as defined by Pacheco (2003, 2015), at the morphological level includes at least two unnamed taxa (*Thomasomys* sp. 1 and *Thomasomys* sp. 2) (Pacheco 2003). Other candidate species found with molecular information (*Cytb* sequences) include *T. aureus* "Sangay" [MN557077], *T. pardignasi*, and *T. cf. princeps* from Ecuador [MN818905].

We found the "aureus" group is paraphyletic with members represented in two non-reciprocal clades, a clade formed by the nominal species *T. aureus* sensu stricto with *T. antoniobracki* sp. nov., *T. praetor*, *T. aureus* "Sangay," *T. cf. princeps*, *T. auricularis*, *T. pardignasi*, *T. pyrrhonotus*, and *Thomasomys* sp. 2; and another formed by *Thomasomys* sp. 1 and *T. apeco*, which, although weakly supported, was more related to the "notatus" and "baeops" groups. Lee et al. (2015, 2018) and Brito et al. (2019, 2021) also found a paraphyletic "aureus" group, but their representatives were very limited. Although this work is the most comprehensive phylogenetic analysis of the "aureus" group, which includes species like *T. apeco*, *T. praetor*, and *T. pyrrhonotus*, assessed for the first time in molecular analyzes, it should be considered preliminary. A complete molecular analysis of the "aureus" group would require the inclusion of *T. nicefori* Thomas, 1921, *T. popayanus* Allen, 1912, *T. princeps* (Thomas, 1895), *T. rosalinda*, and the candidate species mentioned by Pacheco (2015) and Brito et al. (2019, 2021).

On the other hand, it is interesting to highlight that the well-supported clade (bs: 97, pp: 1) of the "aureus" group (removing *T. apeco*, *Thomasomys* sp. 1, and *Thomasomys* sp. 2) include species distributed at western Río Marañón, in the Piura, Cajamarca, Lambayeque, and La Libertad departments. While *T. apeco* and *Thomasomys* sp. 1 are distributed east and south of the Río Marañón. This pattern could reinforce the hypothetical biogeographic role of the Río Marañón as a barrier for sigmodontine rodents suggested by some authors (e.g., Hurtado & Pacheco 2017; Jiménez et al. 2013; Rengifo & Pacheco 2015; Pacheco 2015; Ruelas et al. 2021). Pacheco 2015, suggested this river and the Huancabamba Depression

(HD) as the limit for distribution of *Thomasomys* species groups, such as the "incanus" (south of HD), "baeops" (north of HD), "gracilis" (south of HD), "macrotis" (between Marañón and Huallaga rivers, south of HD), and "notatus" (south of HD) groups. While "cinereus" and "aureus" groups are widely distributed across the HD and the Río Marañón. Nevertheless, a new hypothesis proposed here, based on our phylogenetic analysis, the paraphyly of the "aureus" group and *T. aureus* sensu lato, suggests the importance of this river on the distribution of species of this group.

*Thomasomys aureus* sensu lato needs to be assessed. *T. aureus* is the species of *Thomasomys* more widely distributed from central Colombia to Bolivia (Pacheco 2015, 2021). Although the type locality of the nominal form of *T. aureus* was not given by Tomes (1860), it was restricted to Pallatanga, Ecuador, by Pacheco (2015). Our analysis has included two specimens from the Río Tatahuazo, Bolívar province, at 30 km from Pallatanga (MSB 70707, 70708) cited by Pacheco (2015) as typical *T. aureus*. In the distribution of *T. aureus*, Pacheco (2003, 2015) included provisionally *Thomasomys* sp. 1 that includes populations from southeastern Peru and Bolivia and *Thomasomys* sp. 2 from Bolivia. Besides, there are other entities identified molecularly as related to *T. aureus* but without a morphological description. The divergence between *T. aureus* "Sangay" (KR818905: ACUNHC 1560) and *T. cf. princeps* (MN557077: MECN 5666) was  $0.26 \pm 0.24\%$ ; both collected in Parque Nacional Sangay, Ecuador (Lee et al. 2015, Brito et al. 2019) with a geographic distance between their collection locality of only 0.71 km. Therefore, we consider both as conspecific following Pacheco (2021), who suggested that *T. cf. princeps* from Ecuador was not adequately identified. We tentatively call this clade *T. aureus* "Sangay," which is sister to *T. aureus* s.s. with a genetic distance of 5.64 % (see Table 3). Pacheco (2021) suggested these could represent *T. aureus* s.s., *T. princeps*, or a new taxon, but based on our genetic data, *T. aureus* "Sangay" is genetically distinct from *T. aureus* s.s. Proper identification would require molecular comparisons with the holotype of *T. princeps* or topotypes from Cundinamarca. To solve the phylogenetic position of *T. aureus* s.s. and the identity of specimens recognized as *T. aureus* from Ecuador, we recommend obtaining the sequence of the holotype (BMNH 7.1.1.104).

Our results also give support to the recognition of *T. auricularis* as a valid species. This species has been treated as a synonym or subspecies of *T. pyrrhonotus* (Cabrera 1961), and following synopses (e.g., Musser & Carleton 1993, 2005); but validated by Gyldenstolpe (1932) and later Pacheco (2003). Posteriorly, Pacheco (2015) provided detailed morphological traits that differentiate *T. auricularis* from *T. pyrrhonotus*, supported here by a genetic distance of 9.19 % in our analysis.

#### Agradecimientos / Acknowledgments:

We thank Joseph Cook and Jonathan L. Dunnum (Museum of Southwestern Biology, New Mexico) for kindly sharing with us sequences and photos of *T. aureus* sensu stricto, and to Rob Voss (American Museum of New York, New York) for allowing VP access to specimens of Thomasomys during his stay as doctoral student. We thank Omar Ruelas for preparing the ratio diagram, Richard Cadenillas, Carlos Tello, and María Peralta for collecting the specimens. This study was partially funded by the contract N° 402-PNICP-PIBA-2014 (INNOVATE-PERU) and the Universidad Nacional Mayor de San Marcos (RR 03202-R-18 and RR 03556-R-19). This study was made under the objectives of the DIMAPA research group of the Vicerrectorado de Investigación y Posgrado of the UNMSM.

#### Conflictos de intereses / Competing interests:

The authors declare no conflict of interest.

#### Rol de los autores / Authors Roles:

DR designed the research, prepared tables and figures, analyzed the data, and drafted the article. VP designed the research, analyzed the data, drafted the article, and critically reviewed the draft. All authors approved the final draft.

#### Fuentes de financiamiento / Funding:

INNOVATE-PERU partially funded this study under the contract N° 402-PNICP-PIBA-2014 and the Universidad Nacional Mayor de San Marcos (RR 03202-R-18 and RR 03556-R-19). The authors declare, this work not received specific funding.

#### Aspectos éticos / legales; Ethics / legal:

There are no ethical or legal aspects to declare when dealing with this article.
