

Distribution and phenology of *Bomarea* (Alstroemeriaceae) in the relict forests of northwestern Peru

Distribución y fenología de *Bomarea* (Alstroemeriaceae) en los bosques relictos de la vertientes noroccidentales del Perú

Anton Hofreiter¹ y Eric F. Rodríguez²

Abstract

The distribution, phenology and diversity of *Bomarea* in the relict forests of northwestern Peru is discussed and compared to the cloud forests of the eastern slope of the Andes. Most species of subgenus *Bomarea* and all species of subgenus *Sphaerine* have southernmost distribution limit in the Cordillera Occidental in the relict forests of NW Peru. The phenology of some species of *Bomarea* species differs between the relict forests and the eastern slopes of the Andes, whereas no differences are observed in *Sphaerine*.

Keywords: *Bomarea*, phenology, Peru, relict forests, Amotape-Huancabamba Zone.

Resumen

Se discute la distribución, fenología y diversidad de *Bomarea* en los bosques relictos de las vertientes occidentales del norte del Perú, y compara con las especies presentes en los bosques nublados de las vertientes orientales. Se considera que los bosques relictos son el límite de distribución meridional en la Cordillera Occidental para el subgénero *Bomarea* s.str., con pocas excepciones y para el subgénero *Sphaerine*. La fenología de una parte de las especies de *Bomarea* s. str., es diferente en las vertientes occidentales y orientales; sin embargo, para las especies de *Sphaerine*, no se encontraron tales diferencias.

Palabras clave: *Bomarea*, fenología, Perú, bosques relictos, región Amotape-Huancabamba.

Introduction

The genus *Bomarea* (Alstroemeriaceae) is largely restricted to the American Cordillera. Its representatives are found from near sea-level to 5200 m in most vegetation types ranging from rain forests to semidesert and from open habitats to the deep shadow of the cloud forests understorey.

The genus *Bomarea* is subdivided into four subgenera and various informal «species groups» (Hofreiter & Tillich, 2002): subg.

Baccata (3 spp.), subg. *Bomarea* (ca. 70 spp.), subg. *Sphaerine* (12 spp.) and subg. *Wichuraea* (18 spp.). Subgenera *Bomarea*, *Sphaerine* and *Wichuraea* have their centres of diversity in Peru, only subgenus *Baccata*, a group of large lowland lianas, is absent from the country. Species of subgen. *Wichuraea* grow mostly in open habitats in puna and jalca and their distribution patterns are essentially identical on the western and the eastern Cordillera (Hofreiter & Tillich, 2003). Species of subgen. *Sphaerine* are found both in páramo and cloud forest habitats, but are restricted to the understorey of cloud forests in northern Peru. Species of subg. *Bomarea* are mostly climbers from the edges of cloud forests.

Whereas many species of *Bomarea* flower more or less throughout the year, there are other taxa which have a certain flowering period,

which is usually dictated by the rainy season. In the northwestern Peru most precipitation falls between December and April, but the rainy season can extend into May, especially in the wetter relict forests (e.g., Monte Seco).

There are several species of this genus in the relict forests of northwestern Peru and the present article deals with their distribution, affinities and phenology.

Material and methods

For this study several hundred herbarium specimen of more than 20 herbaria have been studied. (Appendix 1; the acronyms of the herbaria follow Holmgren et al. 1990). Additional the plant were studied in the field, between October 2004 and June 2005 various relict forests were examined (see Table 1). Additional, material was conserved in alcohol or FAA to study the flower and trichome structure in detail. The distribution and phenology of 10 *Bomarea* species who are restricted to the relict forest of the Amotape-Huancabamba-region according to Weigend (2002, 2004) is presented and discussed.

Distribution Patterns

In northwestern Peru both subgenera (*Bomarea* and *Sphaerine*) are restricted to relict forests with one exception in *Bomarea* s.str. (*B. ovata*). Both subgenera reach their southern distribution limit in the western Cordillera in northwestern Peru, with some exceptions in *Bomarea* s.str. (*B. ovata* in the western Cordillera of central and southern Peru and *B. ovallei* and *B. salsilla* in Chile). In the relict forests occur 10 *Bomarea* s.str. species (Table 1). They are members of 3 different groups: *Edulis* group (*B. campanularia*, *B. cf. cornuta* and *B. tribachiata*), *Goniocaulon* group (*B. angulata*, *B. goniocaulon* and *B. multipes*) and *Multiflora* group (*B. densiflora*, *B. dissitifolia*, *B. setacea* and *B. superba*). The *Multiflora* group is distributed from Mexico to Bolivia and all species are restricted to cloud forests. In northwestern Peru the species of

this group occur reach south to San Miguel (Province San Miguel, Department Cajamarca). In the Bosque de Cutervo there are five typical cloud forest species, all four species of the *Multiflora* group and *B. distichifolia* of subg. *Sphaerine*, all these species are absent from the Bosque de Cachil (Province Contumazá, Department Cajamarca) and further south. Some species of the *Multiflora* group are restricted to the eastern slopes of the western Amotape-Huancabamba Zone (west of the Marañon valley): Thus one species of the *B. setacea* complex is very abundant in Cutervo, but no species of this group is found in the Bosque de Monte Seco. *B. distichifolia* (*Sphaerine*) occurs on the eastern side of the Andes from southern Ecuador to central Bolivia and on the western slopes finds its southern limit in the Bosque de Monte Seco (Department Cajamarca).

Both *B. distichifolia* and the species of the *Multiflora* group have their centres of diversity in the cloud forests of the Cordillera Oriental: In the eastern cloud forests at least 4 *Multiflora* species and 5 *Sphaerine* species occur which are found not in the relict forests. In the relict forests these groups appear to have relict populations and are there restricted to the wettest forests. Many typical cloud forest species and species groups of *Bomarea* are completely absent from the northwest Peruvian relict forests: *B. pardina* is distributed in lower cloud forests from southern Colombia to southern Peru. Its westernmost known population is in the cloud forests of Tabaconas (Province Jaén, Department Cajamarca). There is also a group of undescribed species with pendent red or orange flowers, aberrantly actinomorphic flowers and an umbel as inflorescence which are restricted to the cloud forests of the eastern Amotape-Huancabamba Zone. *B. tribachiata* is endemic in the western relict forests. The closest relatives of this species are the widely distributed species of the *Edulis* group. *B. cf. cornuta* is very similar to the wide distributed *B. ovata*.

Table 1. Characteristics of the species of *Bomarea* of the relict forest of northwestern Peru.

Subgenus	Species Group	Species	Distribution Relict Forests	General Distribution	Relict Forests	Flowering Time Elsewhere
<i>Bomarea</i>	<i>Goniocaulon</i>	<i>ungulata</i>	<i>San Andrés</i> (Cutervo) <i>Tongod</i> (San Miguel) <i>Agua Blanca</i> (San Miguel) <i>Cachil</i> (Contumazá)	Anotape-Huancabamba Zone (Ecuador, Peru) N Peru, Ecuador	June-July end of the dry season	all year, peak at the end of the dry season

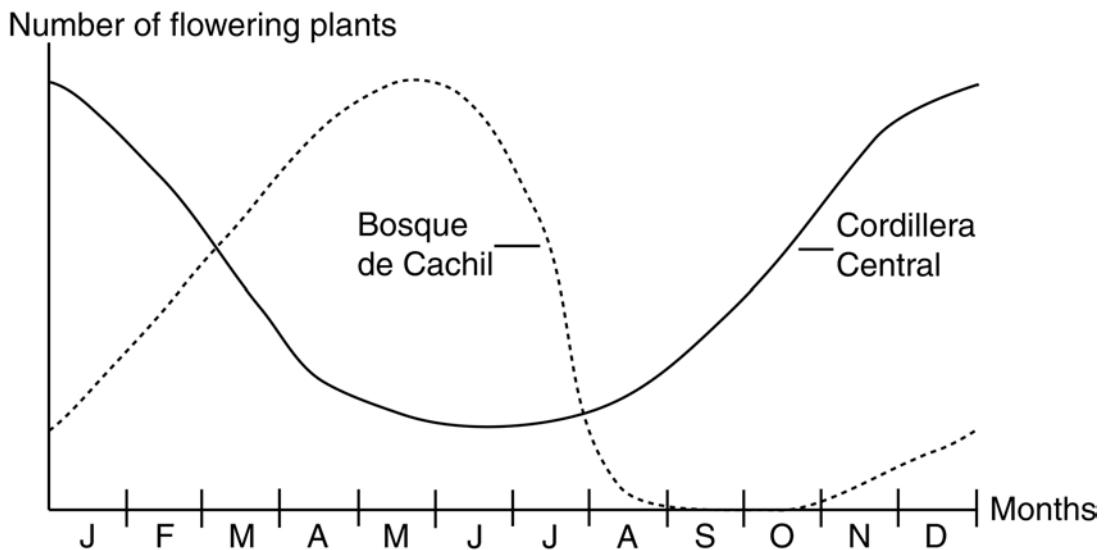

Figure 1. Comparison of the phenology in the time between the species of *Bomarea* of the relict forests of northwestern (e.g. Bosque de Cachil, Prov. Contumazá, Depto. Cajamarca) and eastern slopes of Peru.

Weigend (2004) roughly groups the plant species of the relict forests into four distributional types: 1. Species typical for the forest of western Ecuador, 2. species typical for the eastern cloud forests, 3. species which its next relatives occur in open habitats and 4. old groups which occur only in the relict cloud forests.

B. campanularia is a member of the first group, *B. distichifolia* and the *Multiflora* group are members of the second group and *B. cf. cornuta* and *B. tribachiata* are members of the third group. The species of the *Goniocaulon* group fit best in the third group, but they are not different enough to be classified as different species.

Phenology

The ecology of some of the species of the subg. *Bomarea* on the western and eastern side of the Andes is very different. The twining species on the eastern slopes are evergreen and they have their peak in flowering at the end of the dry season and the beginning of the rainy season (September—October, December), but individual flowering plants can be found nearly the all around the year, with little flowering in May—July (Table 1). In the relict

forest of Contumazá the plants of subg. *Bomarea* are completely dry at the end of the dry season and their peak flowering period is at the end of the rainy season in May—June (Fig. 1).

The species of the *Multiflora* group have also in the relict forest their peak in flowering at the end of the dry season or are flowering the whole year around, but they only occur in the wetter northern part. Other species like *B. tribachiata* (*Edulis* group) flower at the end of the rainy season in the whole area. So we can distinguish 3 different forests in northern Peru according to the phenology of *Bomarea*. The wet cloud forests were all species have their peak in flowering at the end of the dry season and the beginning of the wet season, the relict forests in Piura and the northern half of Cajamarca, where the *Multiflora* group has its peak at the end of the dry season and the beginning of the wet season and the other species of *Bomarea* flower at the end of the rainy season, and the relict forest in southern Cajamarca and La Libertad were all species flower at the end of the wet season. *B. distichifolia* (*Sphaerine*) flowers in the eastern and the western cordi-

llera the whole year around. It only occurs in permanently wet cloud forests.

Acknowledgements

We thank the directors and curators of the herbaria AAU, B, BM, CUZ, E, F, G, GH, HAO, HBG, HUT, K, LP, LZ, M, MA, MO, NY, U, UC, US, USM and W. We thank H-J. Tillich for critical comments, A. Davies for revising the English text, H. Förther for his help with taxonomic problems, C. Köbele for assistance at computer problems, F.J. Höck for taking photos of herbarium specimens. We are grateful to A. Cano, F. Careras, N. Salinas and M. I. Torres for diverse help and assistance in Peru, and to S. Beck in Bolivia. The first author is indebted to his parents for their constant support and to Susanna Tausendfreund, his former employer, who accepted very flexible working times, making this research work possible.
